

# Secure Computation - III

CS 601.642/442 Modern Cryptography

Fall 2018

# Securely Computing *any* Function

How can a group of parties securely compute *any* function over their private inputs?

- **Last time:** Yao's Garbled Circuits based solution. Requires little interaction, but only tailored to two-party case.
- **Today:** Goldreich-Micali-Wigderson (GMW) solution. Highly interactive. But extends naturally to  $n > 2$  parties (where up to  $n - 1$  parties may be corrupted).

# Circuit Representation

Function  $f(x, y)$  can be written as a boolean circuit  $C$ :

- *Input*: Input wires of  $C$  correspond to inputs  $x$  and  $y$  to  $f$
- *Gates*:  $C$  contains AND and NOT gates, where each gate has fan in at most 2 and arbitrary fan out

- *Output*: Output wires of  $C$  correspond to output of  $f(x, y)$

# Secret Sharing

A  $k$ -out-of- $n$  secret sharing scheme allows for “dividing” a secret value  $s$  into  $n$  parts  $s_1, \dots, s_n$  s.t.

- **Correctness:** Any subset of  $k$  shares can be “combined” to reconstruct the secret  $s$
- **Privacy:** The value  $s$  is completely hidden from anyone who only has at most  $k - 1$  shares of  $s$

Think: How to formalize?

# Secret Sharing: Definition

## Definition

A  $(k, n)$  secret-sharing consists of a pair of PPT algorithms (Share, Reconstruct) s.t.:

- Share( $s$ ) produces an  $n$  tuple  $(s_1, \dots, s_n)$
- Reconstruct( $s'_{i_1}, \dots, s'_{i_k}$ ) is s.t. if  $\{s'_{i_1}, \dots, s'_{i_k}\} \subseteq \{s_1, \dots, s_n\}$ , then it outputs  $s$
- For any two  $s$  and  $\tilde{s}$ , and for any subset of at most  $k - 1$  indices  $X \subset [1, n]$ ,  $|X| < k$ , the following two distributions are statistically close:

$$\left\{ (s_1, \dots, s_n) \leftarrow \text{Share}(s) : (s_i | i \in X) \right\},$$
$$\left\{ (\tilde{s}_1, \dots, \tilde{s}_n) \leftarrow \text{Share}(\tilde{s}) : (\tilde{s}_i | i \in X) \right\}.$$

# Secret Sharing: Construction

An  $(n, n)$  secret-sharing scheme for  $s \in \{0, 1\}$  based on XOR:

- **Share**( $s$ ): Sample random bits  $(s_1, \dots, s_n)$  s.t.  $s_1 \oplus \dots \oplus s_n = s$
- **Reconstruct**( $s'_1, \dots, s'_n$ ): Output  $s'_1 \oplus \dots \oplus s'_n$

Think: Security?

# GMW Protocol: Outline

GMW protocol consists of three phases:

- **Input Sharing:** Each party *secret-shares* its input into two parts and sends one part to the other party
- **Circuit evaluation:** The parties evaluate the circuit in a *gate-by-gate* fashion in such a manner that for every internal wire  $w$  in the circuit, each party holds a secret share of the value of wire  $w$
- **Output reconstruction:** Finally, the parties exchange the secret shares of the output wires. Each party then, on its own, combines the secret shares to compute the output of the circuit

# GMW Protocol: Details

## Notation:

- **Protocol Ingredients:** A  $(2, 2)$  secret-sharing scheme (Share, Reconstruct), and a 1-out-of-4 OT scheme ( $\text{OT} = (S, R)$ )
- **Common input:** Circuit  $C$  for function  $f(\cdot, \cdot)$  with two  $n$ -bit inputs and an  $n$ -bit output
- **$A$ 's input:**  $x = x_1, \dots, x_n$  where  $x_i \in \{0, 1\}$
- **$B$ 's input:**  $y = y_1, \dots, y_n$  where  $y_i \in \{0, 1\}$

**Protocol Invariant:** For every wire in  $C(x, y)$  with value  $w \in \{0, 1\}$ ,  $A$  and  $B$  have shares  $w^A$  and  $w^B$ , respectively, s.t.  
 $\text{Reconstruct}(w^A, w^B) = w$

## GMW Protocol: Details (contd.)

**Protocol  $\Pi = (A, B)$ :**

**Input Sharing:**  $A$  computes  $(x_i^A, x_i^B) \leftarrow \text{Share}(x_i)$  for every  $i \in [n]$  and sends  $(x_1^B, \dots, x_n^B)$  to  $B$ .  $B$  acts analogously.

**Circuit Evaluation:** Run the `CircuitEval` sub-protocol.  $A$  obtains  $\text{out}_i^A$  and  $B$  obtains  $\text{out}_i^B$  for every output wire  $i$ .

**Output Phase:** For every output wire  $i$ ,  $A$  sends  $\text{out}_i^A$  to  $B$ , and  $B$  sends  $\text{out}_i^B$  to  $A$ . Each party computes

$$\text{out}_i = \text{Reconstruct}(\text{out}_i^A, \text{out}_i^B)$$

The output is  $\text{out} = \text{out}_1, \dots, \text{out}_n$

# CircuitEval: NOT Gate

**NOT Gate:** Input  $u$ , output  $w$

- $A$  holds  $u^A$ ,  $B$  holds  $u^B$
- $A$  computes  $w^A = u^A \oplus 1$
- $B$  computes  $w^B = u^B$

Observe:  $w^A \oplus w^B = u^A \oplus 1 \oplus u^B = \bar{u}$

## CircuitEval: AND Gate

**AND Gate:** Inputs  $u, v$ , output  $w$

- $A$  holds  $u^A, v^A$ ,  $B$  holds  $u^B, v^B$
- $A$  samples  $w^A \xleftarrow{\$} \{0, 1\}$  and computes  $w_1^B, \dots, w_4^B$  as follows:

$u^B$	$v^B$	$w^B$
0	0	$w_1^B = w^A \oplus ((u^A \oplus 0) \cdot (v^A \oplus 0))$
0	1	$w_2^B = w^A \oplus ((u^A \oplus 0) \cdot (v^A \oplus 1))$
1	0	$w_3^B = w^A \oplus ((u^A \oplus 1) \cdot (v^A \oplus 0))$
1	1	$w_4^B = w^A \oplus ((u^A \oplus 1) \cdot (v^A \oplus 1))$

- $A$  and  $B$  run OT =  $(S, R)$  where  $A$  acts as sender  $S$  with inputs  $(w_1^B, \dots, w_4^B)$  and  $B$  acts as receiver  $R$  with input  $b = 1 + 2u^B + v^B$

# Intuition for Security

For every wire in  $C$  (except the input and output wires), each party only holds a secret share of the wire value:

- **NOT gate:** Follows from construction
- **AND gate:** Follows from security of OT

At the end, the parties only learn the values of the output wires

Exercise: Construct Simulator for  $\Pi$  using Simulator for OT and prove indistinguishability
