

---

# Image Texture Fundamentals

# Texturing

---

**Allows higher-frequency color variation**

- **Not just interpolated from vertex colors**

**May be 2D (surface-based) or 3D (volume-based)**

- **(or even 4D for light fields -- that's a different lecture)**

**May be strictly image-based or procedural**

- **Today we'll talk about simple image-based**
-

# 2D Texture Mapping

---

**Requires surface parameterization**

- **Mapping from 3D surface to 2D parametric domain**

**Colors defined in 2D parameter space**

**Parameterization (texture coordinates)  
used to determine material color at point  
on surface**

# 2D Texture Diagram

# 2D Texture Applications

---

**Most useful for colors that are sitting on the surface, rather than running through the material**

- **Pictures on the wall**
- **Printed/painted logos, text, etc.**
- **Fake wood grain**

# 2D Texture Example

+

=

# Other Types of 2D Maps

---

## Bump/normal maps

- Modify or define surface normals

## Displacement maps

- Modify surface itself

## Environment/reflection maps

- Define environment seen in specular reflections

# 3D Texture Maps

---

**Colors defined in 3D space**

**3D coordinates of surface used for mapping**

**Usually convenient to define 3D texture in  
object space**

# Bump (normal) Map Example

---

# 3D Texture Applications

---

**More like carving object out of material  
than pasting a picture on the surface**

- **wood, marble, etc.**
- **clouds, fog, fire (hypertextures, using additional density information)**

# Image-based Texture Mapping (2D)

---

**2D texel array (image) determines colors in texture domain**

**Given texture coordinates on surface, look up color in image**

**Lookup may be return nearest texel (*point sampled*) or bilinear interpolation of 4 surrounding texels**

# Acquiring Texture Images

---

## Photograph

- flat surface
- even lighting (no specularities)

## 3D Rendering

## Procedural synthesis

- Sample a procedural texture

# Texture Sampling

from Heckbert, Paul. *Fundamentals of Texture Mapping and Image Warping*. Masters Thesis. UC Berkeley. 1989. page 7.

# Sampling Approaches

---

## Point Sampling

- Pick closest texel
- (Replication/pixel zoom for upsampling)

## Interpolation

- Blend closest texels

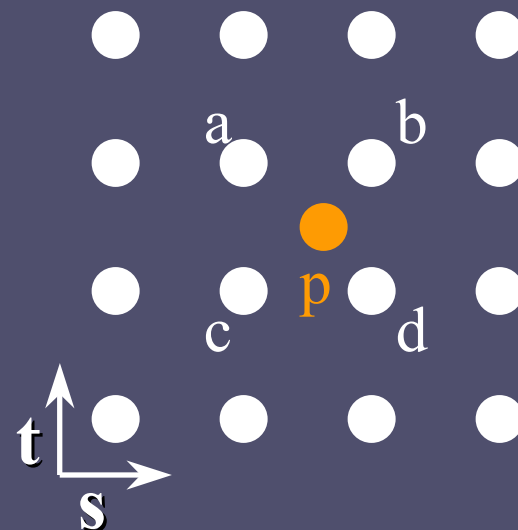

## Area Sampling

- Blend all covered texels

# Bilinear Interpolation

$$p = (p_s, p_t)$$

$$p' = ( (p_s - a_s) / (b_s - a_s), (p_t - a_t) / (c_t - a_t) )$$

$$p_{\text{color}} = \text{lerp}(\text{lerp}(a_{\text{color}}, b_{\text{color}}, p_s'), \text{lerp}(c_{\text{color}}, d_{\text{color}}, p_s'), p_t')$$

$$\text{lerp}(k_1, k_2, t) = (1-t)*k_1 + t*k_2$$

# Texture Area Sampling

---

If frequency of texture content is higher than sampling rate, may want better filtering

Pixel-sized area on surface covers some area in texture domain

- Curvilinear quadrilateral or ellipse

Perform weighted average of texels covered by pixel-sized piece of surface

---

# Mip-mapped Texture Filtering

---

**M**ultim **i**m **p**arvo (many things in a small place)

Pre-compute *image pyramid* to filter texture to various resolutions

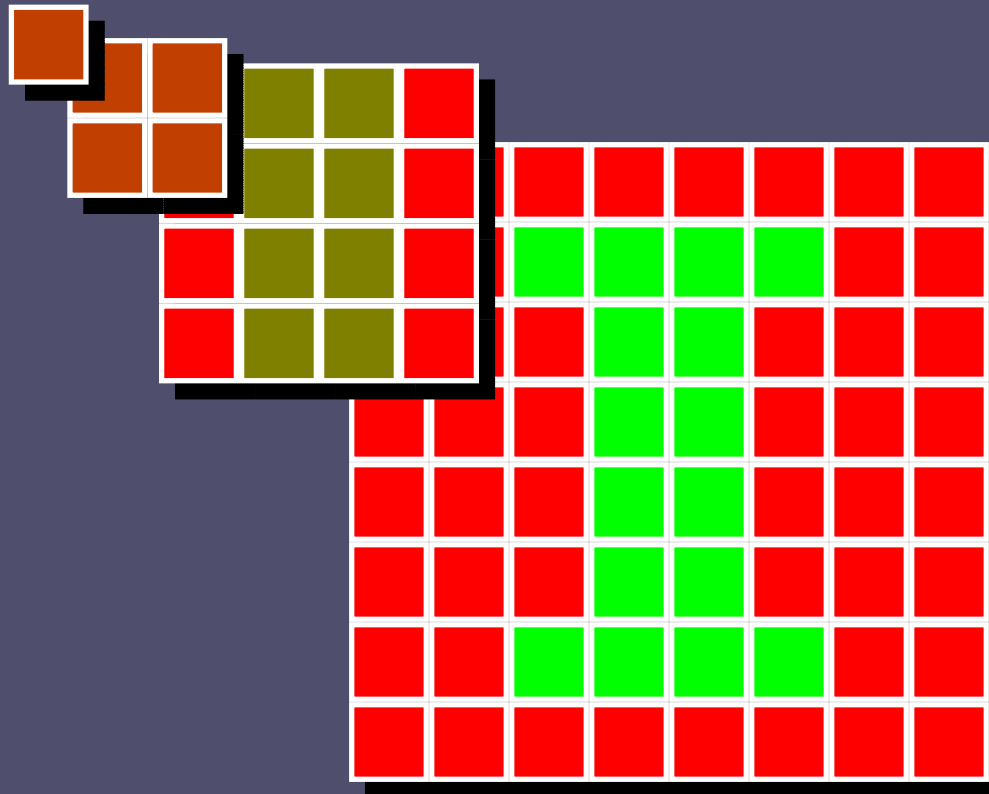

Look up colors from the appropriate level(s) of the image pyramid

Approximation to accurate area sampling

---

# Image Pyramid

parent color = average(4 children colors)

# Mip-map Organization

# Mip-map Filtering Methods

---

Compute  $d$ , the parameter along level space

Sample texture

Option 1: Point sample nearest level

Option 2: Point sample each adjacent level, then linearly interpolate between them

Option 3: Choose nearest level, then bilinearly interpolate within that level

Option 4: Trilinearly interpolate between the 8 samples of two adjacent mip-map levels (2 bilinear interps + 1 linear)

# Computing d

---

Somewhat tricky, because a circular footprint on the screen is elliptical in the texture domain

Typically either over-filter or under-filter

One possible formulation:

$$d = \max \left( \sqrt{(du/dx)^2 + (dv/dx)^2}, \sqrt{(du/dy)^2 + (dv/dy)^2} \right)$$

(i.e. use the larger of the ellipse dimensions)

---

# Limitations of Mip-Mapping

---

**Assumes circular footprint of pixel in texture domain**

- produces only *isotropic* filtering
- will either over-filter or under-filter in some regions (blurry or jaggy)

# Efficient Anisotropic Filtering

Use multiple mip-map lookups to produce a non-symmetric filter

Video example: Feline

Figure 19: Trilinear paints blurry text.

Figure 21: "High-efficiency" Simple Feline paints smooth text.

# 3D Image-based Texture Mapping

---

**Store data in a 3D image (voxel grid)**

**Point sample using nearest voxel**

**Linearly interpolate using 8 nearest voxels**

**Pre-filtering possible using 3D analog to  
mip-mapping**

# Acquiring 3D images

---

**Slice and photograph real materials**

- e.g. - The Visible Human

**Measure density volume using CT scan or MRI, then map densities to colors**

**Sample a procedurally-generated volume**

# Canonical Parameterizations

---

## Three common primitives:

- Plane
- Cylinder
- Sphere

# Plane Parameterization

---

Suppose we have a plane with origin  $O$  and non-collinear axes,  $i$  and  $j$

- $(x,y,z) = (O_x + si_x + tj_x, O_y + si_y + tj_y, O_z + si_z + tj_z)$
- $(u,v) = (s,t)$

# Cylinder Parameterization

---

Suppose we have a circular cylinder of height  $h$  about  $z$ -axis (with base at  $z=0$ )

- $(x,y,z) = (r\cos\theta, r\sin\theta, z)$
- $(u,v) = (\theta/2\pi, z/h)$

Or we can choose to cover only a portion of the cylinder:

- $(u,v) = ( a(\theta-\theta_0)/2\pi, b(z-z_0)/h )$

# Sphere Parameterization

---

We can similarly parameterize the sphere:

- $(x,y,z) = (r\cos\theta\sin\phi, r\sin\theta\sin\phi, r\cos\phi)$
- $(u,v) = ( \theta/2\pi, \phi/\pi )$

**Note: parameterization degenerate at poles**

- “you can’t comb the hair on a sphere”

**Cover portion of sphere with texture:**

- $(u,v) = ( a*(\theta- \theta_0)/2\pi, b*(\phi-\phi_0)/\pi )$

# Two-stage Mapping

---

1. Map texture onto canonical primitive (the *intermediate surface*)
2. Map intermediate surface to arbitrary object
  - Position objects with respect to each other
  - Project along normal direction (of either one)

# Two-stage Example

# Atlas Approaches

---

**Break complex surface into patches**

**Parameterize / texture each patch**

- **Parameterizations optimized to minimize distortions**

**Atlas describes mapping between texture domains and surface domain**

# Atlas Example

---

from Pederson, “Decorating Implicit Surfaces”, *Proceedings of SIGGRAPH 95*.

---

# Other Texturing Options

---

**Application Modes: relationship between texture colors and surface colors**

- **Decal** - texture color replaces surface color
- **Blend** - colors are combined (e.g. multiplied)

**Wrap modes: what to do with parameters outside of [0,1]**

- **Clamp**
- **Repeat**
