# Constraint Satisfaction

Philipp Koehn

2 March 2017

# Outline

1

- Constraint satisfaction problems (CSP) examples
- Backtracking search for CSPs
- Problem structure and problem decomposition
- Local search for CSPs

# examples

# Example: Map-Coloring

- Variables  $WA, NT, Q, NSW, V, SA, T$
- Domains  $D_i = \{red, green, blue\}$
- Constraints: adjacent regions must have different colors  
e.g.,  $WA \neq NT$  (if the language allows this), or  
 $(WA, NT) \in \{(red, green), (red, blue), (green, red), (green, blue), \dots\}$

# Example: Map-Coloring

- **Solutions** are assignments satisfying all constraints, e.g.,  
 $\{WA = red, NT = green, Q = red, NSW = green, V = red, SA = blue, T = green\}$

# Constraint Satisfaction Problems (CSPs)

- Previously: generic search
  - state is a “black box”
  - state must support goal test, eval, successor■
- CSP
  - **state** is defined by variables  $X_i$  with values from domain  $D_i$
  - **goal test** is a set of **constraints** specifying allowable combinations of values for subsets of variables■
- Simple example of a **formal representation language**
- We will look at useful **general-purpose** algorithms with more power than standard search algorithms

# Varieties of CSPs

- Discrete variables
  - finite domains; size  $d \implies O(d^n)$  complete assignments
    - \* e.g., Boolean CSPs, incl. Boolean satisfiability (NP-complete)■
  - infinite domains (integers, strings, etc.)
    - \* e.g., job scheduling, variables are start/end days for each job
    - \* need a **constraint language**, e.g.,  $StartJob_1 + 5 \leq StartJob_3$
    - \* **linear** constraints solvable, **nonlinear** undecidable■
- Continuous variables
  - e.g., start/end times for Hubble Telescope observations
  - linear constraints solvable in poly time by LP methods

# Varieties of Constraints

- **Unary** constraints involve a single variable,  
e.g.,  $SA \neq \textit{green}$
- **Binary** constraints involve pairs of variables,  
e.g.,  $SA \neq WA$
- **Higher-order** constraints involve 3 or more variables,  
e.g., cryptarithmic column constraints
- **Preferences** (soft constraints), e.g., *red* is better than *green*  
often representable by a cost for each variable assignment  
→ constrained optimization problems

# Map Coloring Constraint Graph

- **Binary CSP:** each constraint relates at most 2 variables (i.e., colors of 2 states)
- **Constraint graph:** nodes are variables, arcs show constraints

- General-purpose CSP algorithms use the graph structure to speed up search. E.g., Tasmania is an independent subproblem!

# Example: Cryptarithmic

$$\begin{array}{r} \text{TWO} \\ + \text{TWO} \\ \hline \text{FOUR} \end{array}$$

- Variables:  $F T U W R O X_1 X_2 X_3$
- Domains:  $\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$
- Constraints  
 $alldiff(F, T, U, W, R, O)$   
 $O + O = R + 10 \cdot X_1$ , etc.

# Example: Sudoku

5	3			7				
6			1	9	5			
	9	8					6	
8				6				3
4			8		3			1
7				2				6
	6					2	8	
			4	1	9			5
				8			7	9

5	3	4	6	7	8	9	1	2
6	7	2	1	9	5	3	4	8
1	9	8	3	4	2	5	6	7
8	5	9	7	6	1	4	2	3
4	2	6	8	5	3	7	9	1
7	1	3	9	2	4	8	5	6
9	6	1	5	3	7	2	8	4
2	8	7	4	1	9	6	3	5
3	4	5	2	8	6	1	7	9

- No same number in row, column, small square
- Easily formulated as CSP with *alldiff* constraints
- Can be quickly solved with standard CSP solvers

# Real-World CSPs

- Assignment problems  
e.g., who teaches what class
- Timetabling problems  
e.g., which class is offered when and where?
- Hardware configuration
- Spreadsheets
- Transportation scheduling
- Factory scheduling
- Floorplanning
  
- Notice that many real-world problems involve real-valued variables

# backtracking search

# Standard Search Formulation (Incremental) 13

- Let's start with the straightforward, dumb approach, then fix it
- States are defined by the values assigned so far
  - **Initial state:** the empty assignment,  $\emptyset$
  - **Successor function:** assign a value to an unassigned variable that does not conflict with current assignment.  
 $\implies$  fail if no legal assignments (not fixable!)
  - **Goal test:** the current assignment is complete■
- Note
  - This is the same for all CSPs! ☺
  - Every solution appears at depth  $n$  with  $n$  variables  
 $\implies$  use depth-first search
  - $b = (n - \ell)d$  at depth  $\ell$ , hence  $n!d^n$  leaves ☹

# Backtracking Search

- Variable assignments are **commutative**, i.e.,  
     $[WA = red \text{ then } NT = green]$  same as  $[NT = green \text{ then } WA = red]$
- Only need to consider assignments to a single variable at each node  
     $\implies b = d$  and there are  $d^n$  leaves
- Depth-first search for CSPs with single-variable assignments  
    is called **backtracking** search
- Backtracking search is the basic uninformed algorithm for CSPs
- Can solve  $n$ -queens for  $n \approx 25$

# Backtracking Search

```
function BACKTRACKING-SEARCH(csp) returns solution/failure
  return RECURSIVE-BACKTRACKING({ }, csp)

function RECURSIVE-BACKTRACKING(assignment, csp) returns soln/failure
  if assignment is complete then return assignment
  var ← SELECT-UNASSIGNED-VARIABLE(VARIABLES[csp], assignment, csp)
  for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do
    if value is consistent with assignment given CONSTRAINTS[csp] then
      add { var = value } to assignment
      result ← RECURSIVE-BACKTRACKING(assignment, csp)
      if result ≠ failure then return result
      remove { var = value } from assignment
  return failure
```

# Backtracking Example

# Backtracking Example

Recall: assign variables in fixed order

# Backtracking Example

Only two valid choices (**red** violates constraint)

# Backtracking Example

And so it continues...

full assignment: done

no valid successor: fail → backtrack

# Improving Backtracking Efficiency

**General-purpose** methods can give huge gains in speed

1. Which variable should be assigned next?
2. In what order should its values be tried?
3. Can we detect inevitable failure early?
4. Can we take advantage of problem structure?

# Minimum Remaining Values

- Minimum remaining values (MRV):  
choose the variable with the fewest legal values

# Degree Heuristic

- Tie-breaker among MRV variables
- Degree heuristic:  
choose the variable with the most constraints on remaining variables

# Least Constraining Value

- Given a variable, choose the least constraining value:  
the one that rules out the fewest values in the remaining variables

- Combining these heuristics makes 1000 queens feasible

# constraint propagation

# Forward Checking

- **Idea:** Keep track of remaining legal values for unassigned variables  
Terminate search when any variable has no legal values

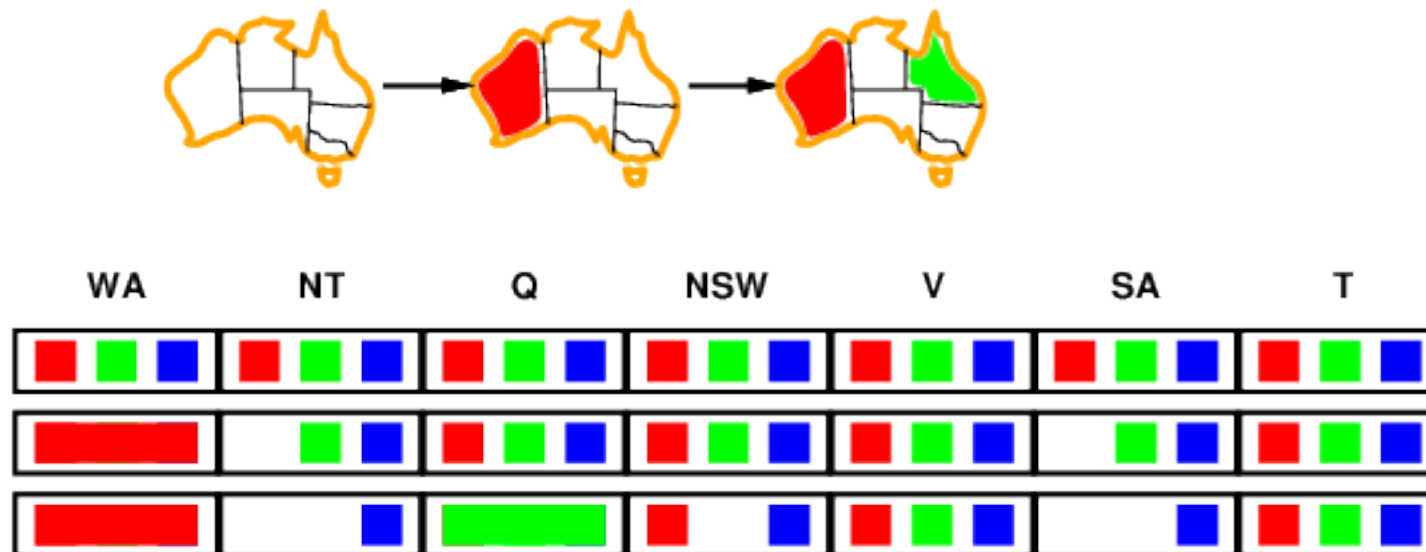

# Forward Checking

- **Idea:** Keep track of remaining legal values for unassigned variables  
Terminate search when any variable has no legal values

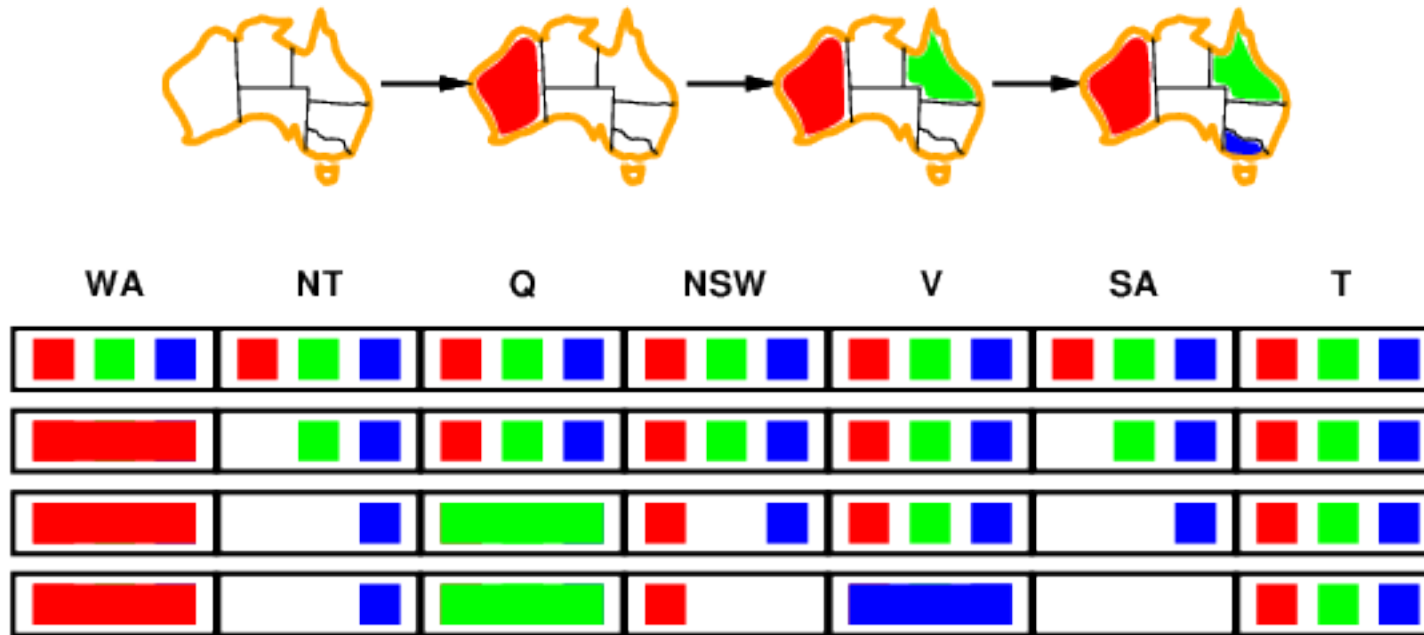

# Forward Checking

- **Idea:** Keep track of remaining legal values for unassigned variables  
Terminate search when any variable has no legal values

# Forward Checking

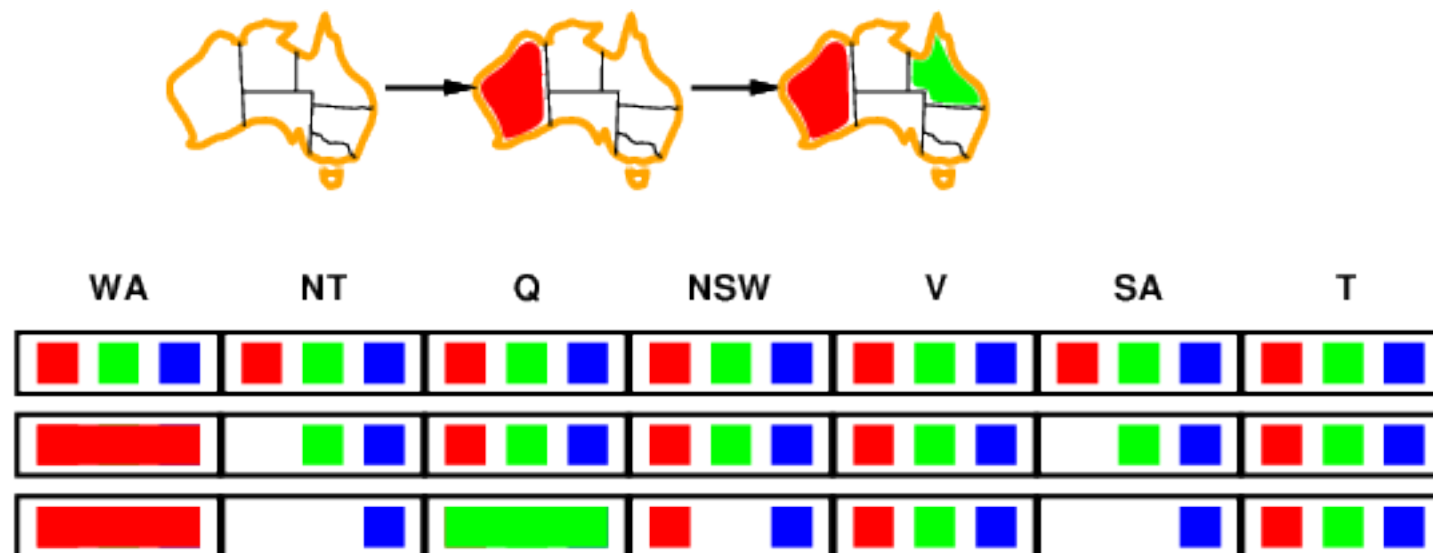

- **Idea:** Keep track of remaining legal values for unassigned variables  
 Terminate search when any variable has no legal values

# Arc Consistency

- Simplest form of propagation makes each arc consistent
- $X \rightarrow Y$  is consistent iff  
for **every** value  $x$  of  $X$  there is **some** allowed  $y$

# Arc Consistency

- Simplest form of propagation makes each arc consistent
- $X \rightarrow Y$  is consistent iff  
for **every** value  $x$  of  $X$  there is **some** allowed  $y$

# Arc Consistency

- Simplest form of propagation makes each arc consistent
- $X \rightarrow Y$  is consistent iff  
for **every** value  $x$  of  $X$  there is **some** allowed  $y$

- If  $X$  loses a value, neighbors of  $X$  need to be rechecked

# Arc Consistency

- Simplest form of propagation makes each arc consistent
- $X \rightarrow Y$  is consistent iff  
for **every** value  $x$  of  $X$  there is **some** allowed  $y$

- If  $X$  loses a value, neighbors of  $X$  need to be rechecked
- Arc consistency detects failure earlier than forward checking
- Can be run as a preprocessor or after each assignment

# Arc Consistency Algorithm

**function** **AC-3**( *csp*) **returns** the CSP, possibly with reduced domains

**inputs:** *csp*, a binary CSP with variables  $\{X_1, X_2, \dots, X_n\}$

**local variables:** *queue*, a queue of arcs, initially all the arcs in *csp*

**while** *queue* is not empty **do**

$(X_i, X_j) \leftarrow \text{REMOVE-FIRST}(\textit{queue})$

**if** **REMOVE-INCONSISTENT-VALUES**( $X_i, X_j$ ) **then**

**for each**  $X_k$  **in** **NEIGHBORS**[ $X_i$ ] **do**

            add  $(X_k, X_i)$  to *queue*

---

**function** **REMOVE-INCONSISTENT-VALUES**(  $X_i, X_j$ ) **returns** true iff succeeds

*removed*  $\leftarrow$  *false*

**for each**  $x$  **in** **DOMAIN**[ $X_i$ ] **do**

**if** no value  $y$  in **DOMAIN**[ $X_j$ ] allows  $(x,y)$  to satisfy the constraint  $X_i \leftrightarrow X_j$

**then** delete  $x$  from **DOMAIN**[ $X_i$ ]; *removed*  $\leftarrow$  *true*

**return** *removed*

$O(n^2d^3)$ , can be reduced to  $O(n^2d^2)$  (but detecting **all** is NP-hard)

# Path Consistency

- Arc consistency check removes some possible values
  - reduces search space
  - may already solve problem (each variable one value)
  - may already eliminate search state (one variable no value)
- One step further: path consistency
- Any two variable set  $\{X_i, X_j\}$  is **path consistent** with third variable  $X_k$  if any assignment  $\{X_i = a, X_j = b\}$  there is an assignment for  $X_k$  that fulfills constraints for  $\{X_i, X_k\}$  and  $\{X_j, X_k\}$
- PC-2 path consistency equivalent for AC-3 algorithm

# $k$ -Consistency

- Node consistency = check all unary constraints
  - Arc consistency = check all binary constraints
  - Path consistency = check all constraints for each 3-variable subset
  - $k$ -consistency = check all constraints for each  $k$ -variable subset
  - But: checking all subsets for high  $k$  increasing computationally expensive
- ⇒ not done in practice

# problem structure

# Problem Structure

- Tasmania and mainland are **independent subproblems**
- Identifiable as **connected components** of constraint graph

# Problem Structure

- Suppose each subproblem has  $c$  variables out of  $n$  total
- Worst-case solution cost is  $n/c \cdot d^c$ , **linear** in  $n$
- E.g.,  $n = 80, d = 2, c = 20$   
 $2^{80} = 4$  billion years at 10 million nodes/sec  
 $4 \cdot 2^{20} = 0.4$  seconds at 10 million nodes/sec

# Tree-Structured CSPs

- **Theorem:** if constraint graph has no loops, CSP can be solved in  $O(n d^2)$  time
- Compare to general CSPs, where worst-case time is  $O(d^n)$
- This property also applies to logical and probabilistic reasoning: an important example of the relation between syntactic restrictions and the complexity of reasoning.

# Algorithm for Tree-Structured CSPs

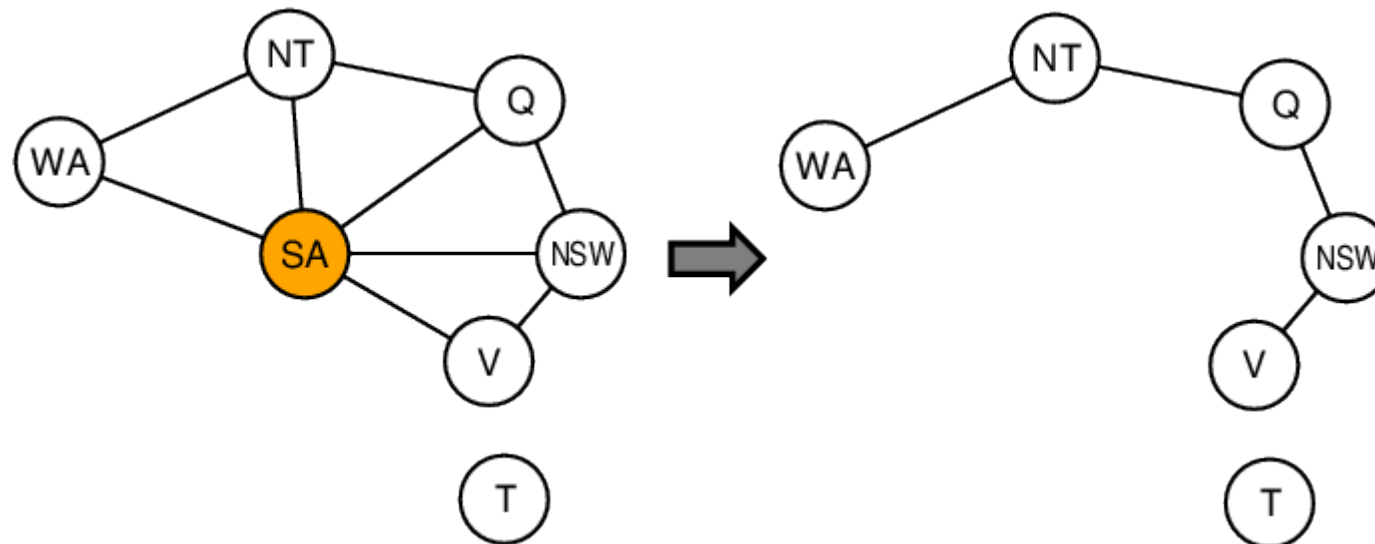

1. Choose a variable as root, order variables from root to leaves such that every node's parent precedes it in the ordering

2. For  $j$  from  $n$  down to  $2$ , apply  $\text{REMOVEINCONSISTENT}(Parent(X_j), X_j)$
3. For  $j$  from  $1$  to  $n$ , assign  $X_j$  consistently with  $Parent(X_j)$

# Nearly Tree-Structured CSPs

- **Conditioning**: instantiate a variable, prune its neighbors' domains

- **Cutset conditioning**: instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree
- Cutset size  $c \implies$  runtime  $O(d^c \cdot (n - c)d^2)$ , very fast for small  $c$

# local search

# Iterative Algorithms for CSPs

- Hill-climbing, simulated annealing typically work with “complete” states, i.e., all variables assigned
- To apply to CSPs
  - allow states with unsatisfied constraints
  - operators **reassign** variable values
- Variable selection: randomly select any conflicted variable
- Value selection by **min-conflicts** heuristic
  - choose value that violates the fewest constraints
  - i.e., hillclimb with  $h(n)$  = total number of violated constraints

# Example: 4-Queens

- **States:** 4 queens in 4 columns ( $4^4 = 256$  states)
- **Operators:** move queen in column
- **Goal test:** no attacks
- **Evaluation:**  $h(n) =$  number of attacks

# Example: 4-Queens as a CSP

- Assume one queen in each column. Which row does each one go in?

- Variables  $Q_1, Q_2, Q_3, Q_4$

- Domains  $D_i = \{1, 2, 3, 4\}$

- Constraints

$Q_i \neq Q_j$  (cannot be in same row)

$|Q_i - Q_j| \neq |i - j|$  (or same diagonal)

- Translate each constraint into set of allowable values for its variables

- E.g., values for  $(Q_1, Q_2)$  are  $(1, 3)$   $(1, 4)$   $(2, 4)$   $(3, 1)$   $(4, 1)$   $(4, 2)$

# Performance of Min-Conflicts

- Given random initial state, can solve  $n$ -queens in almost constant time for arbitrary  $n$  with high probability (e.g.,  $n = 10,000,000$ )
- The same appears to be true for any randomly-generated CSP **except** in a narrow range of the ratio

$$R = \frac{\text{number of constraints}}{\text{number of variables}}$$

# Summary

- CSPs are a special kind of problem:
  - states defined by values of a fixed set of variables
  - goal test defined by **constraints** on variable values
- **Backtracking** = depth-first search with one variable assigned per node
- **Variable ordering** and **value selection** heuristics help significantly
- **Forward checking** prevents assignments that guarantee later failure
- Constraint propagation (e.g., **arc consistency**) does additional work to constrain values and detect inconsistencies
- The CSP representation allows analysis of **problem structure**
- **Tree-structured CSPs** can be solved in linear time
- **Iterative min-conflicts** is usually effective in practice
