
Bayesian Networks

Philipp Koehn

2 April 2019

Outline

1

- Bayesian Networks
- Parameterized distributions
- Exact inference
- Approximate inference

bayesian networks

Bayesian Networks

3

- A simple, graphical notation for conditional independence assertions and hence for compact specification of full joint distributions
- Syntax
 - a set of nodes, one per variable
 - a directed, acyclic graph (link \approx “directly influences”)
 - a conditional distribution for each node given its parents:
 $\mathbf{P}(X_i | Parents(X_i))$
- In the simplest case, conditional distribution represented as a **conditional probability table** (CPT) giving the distribution over X_i for each combination of parent values

Example

- Topology of network encodes conditional independence assertions:

- *Weather* is independent of the other variables
- *Toothache* and *Catch* are conditionally independent given *Cavity*

Example

- *I'm at work, neighbor John calls to say my alarm is ringing, but neighbor Mary doesn't call. Sometimes it's set off by minor earthquakes.*

Is there a burglar?■

- Variables: *Burglar, Earthquake, Alarm, JohnCalls, MaryCalls■*

- Network topology reflects “causal” knowledge

- A burglar can set the alarm off
- An earthquake can set the alarm off
- The alarm can cause Mary to call
- The alarm can cause John to call

Example

Compactness

- A conditional probability table for Boolean X_i with k Boolean parents has 2^k rows for the combinations of parent values
- Each row requires one number p for $X_i = true$ (the number for $X_i = false$ is just $1 - p$)
- If each variable has no more than k parents, the complete network requires $O(n \cdot 2^k)$ numbers
- I.e., grows linearly with n , vs. $O(2^n)$ for the full joint distribution
- For burglary net, $1 + 1 + 4 + 2 + 2 = 10$ numbers (vs. $2^5 - 1 = 31$)

Global Semantics

- **Global** semantics defines the full joint distribution as the product of the local conditional distributions:

$$P(x_1, \dots, x_n) = \prod_{i=1}^n P(x_i | \text{parents}(X_i))$$

- E.g., $P(j \wedge m \wedge a \wedge \neg b \wedge \neg e)$ ■

$$= P(j|a)P(m|a)P(a|\neg b, \neg e)P(\neg b)P(\neg e)$$

$$= 0.9 \times 0.7 \times 0.001 \times 0.999 \times 0.998$$

$$\approx 0.00063$$

Local Semantics

- **Local** semantics: each node is conditionally independent of its nondescendants given its parents

- Theorem: **Local semantics** \Leftrightarrow **global semantics**

Markov Blanket

- Each node is conditionally independent of all others given its **Markov blanket**: parents + children + children's parents

Constructing Bayesian Networks

- Need a method such that a series of locally testable assertions of conditional independence guarantees the required global semantics
 1. Choose an ordering of variables X_1, \dots, X_n
 2. For $i = 1$ to n
 - add X_i to the network
 - select parents from X_1, \dots, X_{i-1} such that
$$\mathbf{P}(X_i | \text{Parents}(X_i)) = \mathbf{P}(X_i | X_1, \dots, X_{i-1})$$
- This choice of parents guarantees the global semantics:

$$\begin{aligned} \mathbf{P}(X_1, \dots, X_n) &= \prod_{i=1}^n \mathbf{P}(X_i | X_1, \dots, X_{i-1}) \quad (\text{chain rule}) \\ &= \prod_{i=1}^n \mathbf{P}(X_i | \text{Parents}(X_i)) \quad (\text{by construction}) \end{aligned}$$

Example

- Suppose we choose the ordering M, J, A, B, E

- $P(J|M) = P(J)$?

Example

- Suppose we choose the ordering M, J, A, B, E

- $P(J|M) = P(J)$? No
- $P(A|J, M) = P(A|J)$? $P(A|J, M) = P(A)$?

Example

- Suppose we choose the ordering M, J, A, B, E

- $P(J|M) = P(J)$? No
- $P(A|J, M) = P(A|J)$? $P(A|J, M) = P(A)$? No
- $P(B|A, J, M) = P(B|A)$?
- $P(B|A, J, M) = P(B)$?

Example

- Suppose we choose the ordering M, J, A, B, E

- $P(J|M) = P(J)$? No
- $P(A|J, M) = P(A|J)$? $P(A|J, M) = P(A)$? No
- $P(B|A, J, M) = P(B|A)$? Yes
- $P(B|A, J, M) = P(B)$? No
- $P(E|B, A, J, M) = P(E|A)$?
- $P(E|B, A, J, M) = P(E|A, B)$?

Example

- Suppose we choose the ordering M, J, A, B, E

- $P(J|M) = P(J)$? No
- $P(A|J, M) = P(A|J)$? $P(A|J, M) = P(A)$? No
- $P(B|A, J, M) = P(B|A)$? Yes
- $P(B|A, J, M) = P(B)$? No
- $P(E|B, A, J, M) = P(E|A)$? No
- $P(E|B, A, J, M) = P(E|A, B)$? Yes

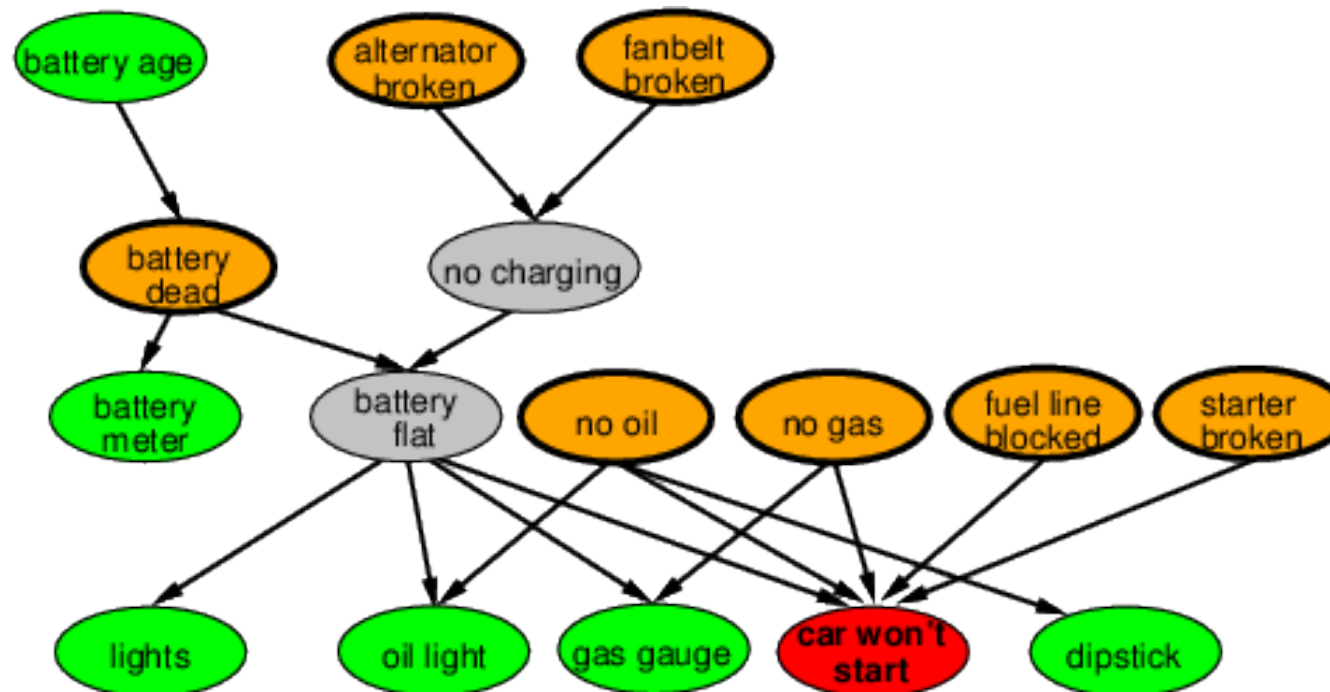

Example

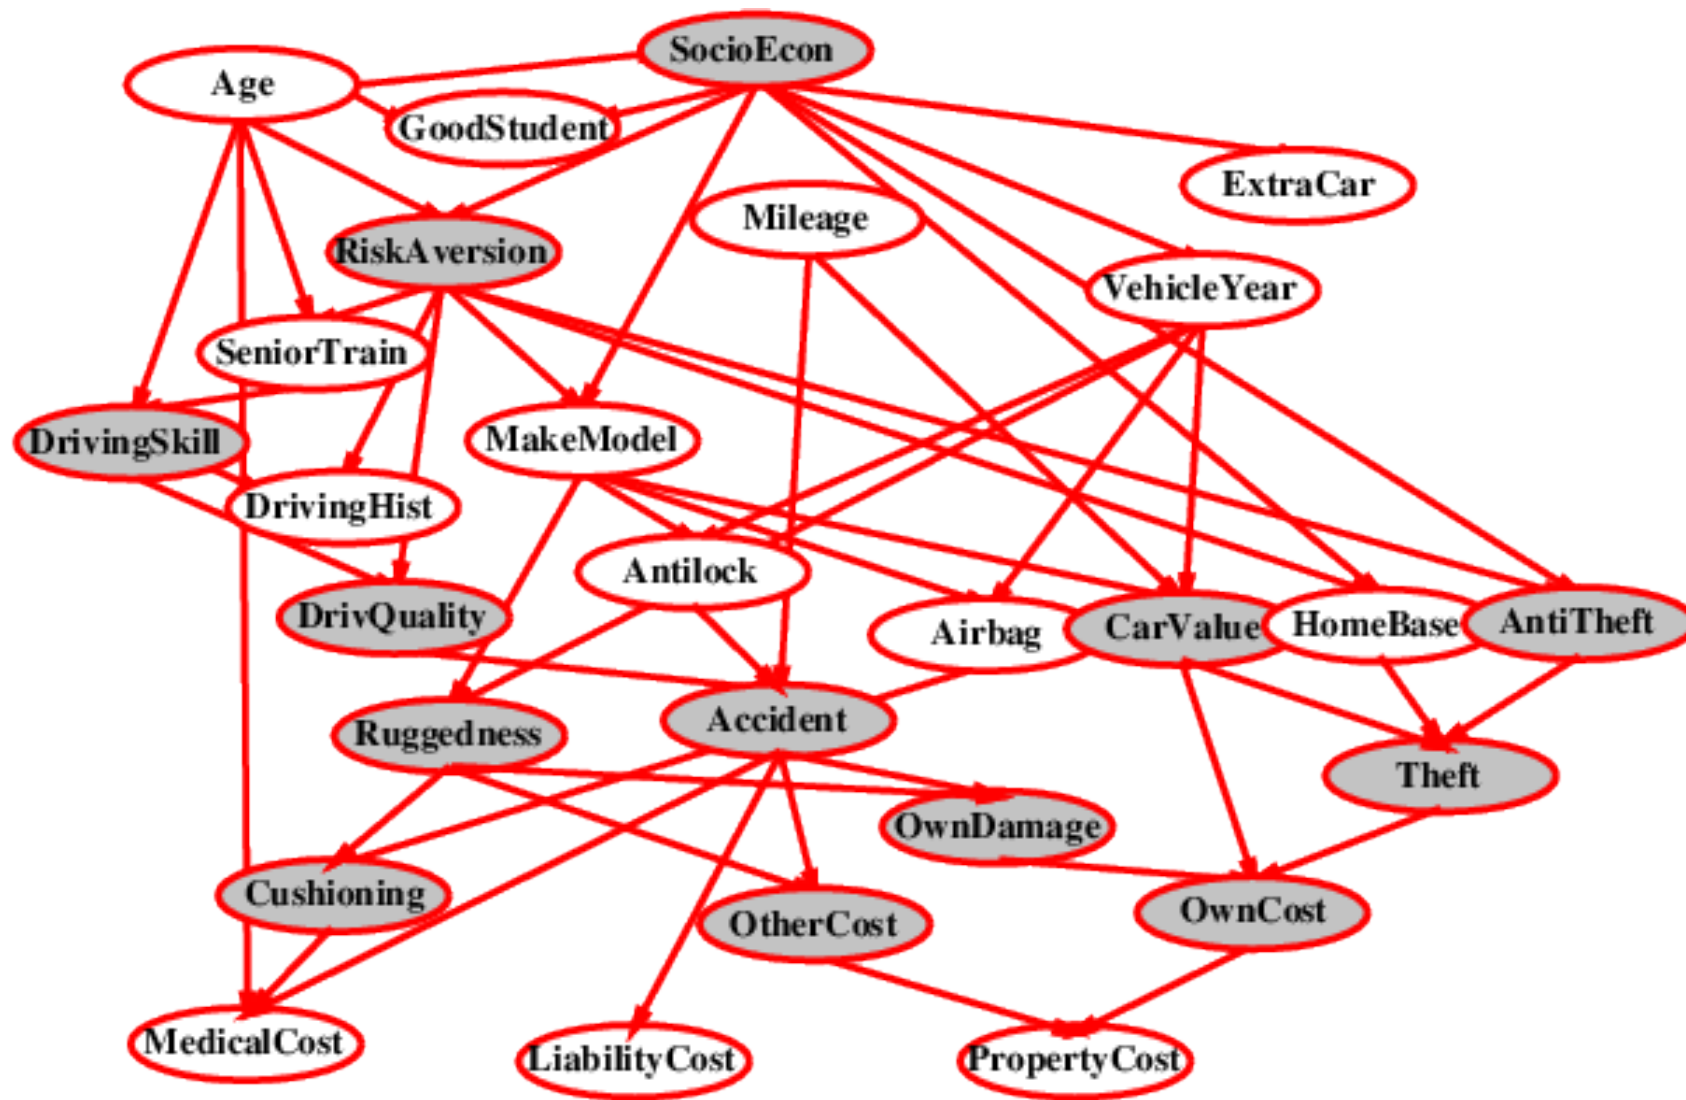

- Deciding conditional independence is hard in noncausal directions
- (Causal models and conditional independence seem hardwired for humans!)
- Assessing conditional probabilities is hard in noncausal directions
- Network is less compact: $1 + 2 + 4 + 2 + 4 = 13$ numbers needed

Example: Car Diagnosis

- Initial evidence: car won't start
- Testable variables (green), "broken, so fix it" variables (orange)
- Hidden variables (gray) ensure sparse structure, reduce parameters

Example: Car Insurance

Compact Conditional Distributions

- CPT grows exponentially with number of parents
CPT becomes infinite with continuous-valued parent or child
- Solution: **canonical** distributions that are defined compactly
- **Deterministic** nodes are the simplest case:
 $X = f(\text{Parents}(X))$ for some function f
- E.g., Boolean functions
 $\text{NorthAmerican} \Leftrightarrow \text{Canadian} \vee \text{US} \vee \text{Mexican}$
- E.g., numerical relationships among continuous variables

$$\frac{\partial \text{Level}}{\partial t} = \text{inflow} + \text{precipitation} - \text{outflow} - \text{evaporation}$$

Compact Conditional Distributions

- Noisy-OR distributions model multiple noninteracting causes
 - parents $U_1 \dots U_k$ include all causes (can add leak node)
 - independent failure probability q_i for each cause alone

$$\implies P(X|U_1 \dots U_j, \neg U_{j+1} \dots \neg U_k) = 1 - \prod_{i=1}^j q_i$$

<i>Cold</i>	<i>Flu</i>	<i>Malaria</i>	$P(\text{Fever})$	$P(\neg \text{Fever})$
F	F	F	0.0	1.0
F	F	T	0.9	0.1
F	T	F	0.8	0.2
F	T	T	0.98	$0.02 = 0.2 \times 0.1$
T	F	F	0.4	0.6
T	F	T	0.94	$0.06 = 0.6 \times 0.1$
T	T	F	0.88	$0.12 = 0.6 \times 0.2$
T	T	T	0.988	$0.012 = 0.6 \times 0.2 \times 0.1$

- Number of parameters **linear** in number of parents

Hybrid (Discrete+Continuous) Networks

- Discrete (*Subsidy?* and *Buys?*); continuous (*Harvest* and *Cost*)

- Option 1: discretization—possibly large errors, large CPTs
Option 2: finitely parameterized canonical families
- 1) Continuous variable, discrete+continuous parents (e.g., *Cost*)
2) Discrete variable, continuous parents (e.g., *Buys?*)

Continuous Child Variables

- Need one **conditional density** function for child variable given continuous parents, for each possible assignment to discrete parents
- Most common is the **linear Gaussian** model, e.g.,:

$$\begin{aligned} P(\text{Cost} = c | \text{Harvest} = h, \text{Subsidy?} = \text{true}) \\ &= N(a_t h + b_t, \sigma_t)(c) \\ &= \frac{1}{\sigma_t \sqrt{2\pi}} \exp\left(-\frac{1}{2} \left(\frac{c - (a_t h + b_t)}{\sigma_t}\right)^2\right) \end{aligned}$$

Continuous Child Variables

- All-continuous network with LG distributions
 - ⇒ full joint distribution is a multivariate Gaussian
- Discrete+continuous LG network is a **conditional Gaussian** network i.e., a multivariate Gaussian over all continuous variables for each combination of discrete variable values

Discrete Variable w/ Continuous Parents

- Probability of *Buys?* given *Cost* should be a “soft” threshold:

- **Probit** distribution uses integral of Gaussian:

$$\Phi(x) = \int_{-\infty}^x N(0, 1)(x)dx$$

$$P(\text{Buys?} = \text{true} \mid \text{Cost} = c) = \Phi((-c + \mu)/\sigma)$$

Why the Probit?

- It's sort of the right shape
- Can view as hard threshold whose location is subject to noise

Discrete Variable

- Sigmoid (or logit) distribution also used in neural networks:

$$P(\text{Buys?} = \text{true} \mid \text{Cost} = c) = \frac{1}{1 + \exp\left(-2\frac{-c+\mu}{\sigma}\right)}$$

- Sigmoid has similar shape to probit but much longer tails:

inference

- **Simple queries:** compute posterior marginal $\mathbf{P}(X_i|\mathbf{E} = \mathbf{e})$
e.g., $P(\text{NoGas}|\text{Gauge} = \text{empty}, \text{Lights} = \text{on}, \text{Starts} = \text{false})$ ■
- **Conjunctive queries:** $\mathbf{P}(X_i, X_j|\mathbf{E} = \mathbf{e}) = \mathbf{P}(X_i|\mathbf{E} = \mathbf{e})\mathbf{P}(X_j|X_i, \mathbf{E} = \mathbf{e})$ ■
- **Optimal decisions:** decision networks include utility information;
probabilistic inference required for $P(\text{outcome}|\text{action}, \text{evidence})$ ■
- **Value of information:** which evidence to seek next?■
- **Sensitivity analysis:** which probability values are most critical?■
- **Explanation:** why do I need a new starter motor?

Inference by Enumeration

- Slightly intelligent way to sum out variables from the joint without actually constructing its explicit representation

- Simple query on the burglary network

$$\begin{aligned} & \mathbf{P}(B|j, m) \\ &= \mathbf{P}(B, j, m) / P(j, m) \blacksquare \\ &= \alpha \mathbf{P}(B, j, m) \blacksquare \\ &= \alpha \sum_e \sum_a \mathbf{P}(B, e, a, j, m) \blacksquare \end{aligned}$$

- Rewrite full joint entries using product of CPT entries:

$$\begin{aligned} & \mathbf{P}(B|j, m) \\ &= \alpha \sum_e \sum_a \mathbf{P}(B)P(e)\mathbf{P}(a|B, e)P(j|a)P(m|a) \blacksquare \\ &= \alpha \mathbf{P}(B) \sum_e P(e) \sum_a \mathbf{P}(a|B, e)P(j|a)P(m|a) \blacksquare \end{aligned}$$

- Recursive depth-first enumeration: $O(n)$ space, $O(d^n)$ time

Enumeration Algorithm

function **ENUMERATION-ASK**(X, \mathbf{e}, bn) **returns** a distribution over X

inputs: X , the query variable

\mathbf{e} , observed values for variables \mathbf{E}

bn , a Bayesian network with variables $\{X\} \cup \mathbf{E} \cup \mathbf{Y}$

$Q(X) \leftarrow$ a distribution over X , initially empty

for each value x_i of X **do**

 extend \mathbf{e} with value x_i for X

$Q(x_i) \leftarrow$ **ENUMERATE-ALL**(**VAR**s[bn], \mathbf{e})

return **NORMALIZE**($Q(X)$)

function **ENUMERATE-ALL**($vars, \mathbf{e}$) **returns** a real number

if **EMPTY?**($vars$) **then return** 1.0

$Y \leftarrow$ **FIRST**($vars$)

if Y has value y in \mathbf{e}

then return $P(y \mid Pa(Y)) \times$ **ENUMERATE-ALL**(**REST**($vars$), \mathbf{e})

else return $\sum_y P(y \mid Pa(Y)) \times$ **ENUMERATE-ALL**(**REST**($vars$), \mathbf{e}_y)

 where \mathbf{e}_y is \mathbf{e} extended with $Y = y$

Evaluation Tree

- Enumeration is inefficient: repeated computation
e.g., computes $P(j|a)P(m|a)$ for each value of e

Inference by Variable Elimination

- Variable elimination: carry out summations right-to-left, storing intermediate results (**factors**) to avoid recomputation

$$\begin{aligned} \mathbf{P}(B|j, m) &= \alpha \underbrace{\mathbf{P}(B)}_B \underbrace{\sum_e P(e)}_E \underbrace{\sum_a \mathbf{P}(a|B, e)}_A \underbrace{P(j|a)}_J \underbrace{P(m|a)}_M \blacksquare \\ &= \alpha \mathbf{P}(B) \sum_e P(e) \sum_a \mathbf{P}(a|B, e) P(j|a) f_M(a) \blacksquare \\ &= \alpha \mathbf{P}(B) \sum_e P(e) \sum_a \mathbf{P}(a|B, e) f_J(a) f_M(a) \blacksquare \\ &= \alpha \mathbf{P}(B) \sum_e P(e) \sum_a f_A(a, b, e) f_J(a) f_M(a) \blacksquare \\ &= \alpha \mathbf{P}(B) \sum_e P(e) f_{\bar{A}JM}(b, e) \text{ (sum out } A) \blacksquare \\ &= \alpha \mathbf{P}(B) f_{\bar{E}\bar{A}JM}(b) \text{ (sum out } E) \blacksquare \\ &= \alpha f_B(b) \times f_{\bar{E}\bar{A}JM}(b) \end{aligned}$$

Variable Elimination Algorithm

```
function ELIMINATION-ASK( $X, \mathbf{e}, bn$ ) returns a distribution over  $X$   
inputs:  $X$ , the query variable  
           $\mathbf{e}$ , evidence specified as an event  
           $bn$ , a belief network specifying joint distribution  $\mathbf{P}(X_1, \dots, X_n)$   
 $factors \leftarrow [ ]$ ;  $vars \leftarrow \text{REVERSE}(\text{VARS}[bn])$   
for each  $var$  in  $vars$  do  
     $factors \leftarrow [\text{MAKE-FACTOR}(var, \mathbf{e}) | factors]$   
    if  $var$  is a hidden variable then  $factors \leftarrow \text{SUM-OUT}(var, factors)$   
return NORMALIZE(POINTWISE-PRODUCT( $factors$ ))
```

Irrelevant Variables

- Consider the query $P(\text{JohnCalls} | \text{Burglary} = \text{true})$

$$P(J|b) = \alpha P(b) \sum_e P(e) \sum_a P(a|b, e) P(J|a) \sum_m P(m|a)$$

Sum over m is identically 1; M is **irrelevant** to the query

- Theorem 1: Y is irrelevant unless $Y \in \text{Ancestors}(\{X\} \cup \mathbf{E})$
- Here
 - $X = \text{JohnCalls}$, $\mathbf{E} = \{\text{Burglary}\}$
 - $\text{Ancestors}(\{X\} \cup \mathbf{E}) = \{\text{Alarm}, \text{Earthquake}\}$ \Rightarrow MaryCalls is irrelevant
- Compare this to backward chaining from the query in Horn clause KBs

Irrelevant Variables

- Definition: moral graph of Bayes net: marry all parents and drop arrows
- Definition: **A** is m-separated from **B** by **C** iff separated by **C** in the moral graph
- Theorem 2: **Y** is irrelevant if m-separated from **X** by **E**

- For $P(\text{JohnCalls} | \text{Alarm} = \text{true})$, both *Burglary* and *Earthquake* are irrelevant

Complexity of Exact Inference

- Singly connected networks (or polytrees)
 - any two nodes are connected by at most one (undirected) path
 - time and space cost of variable elimination are $O(d^k n)$
- Multiply connected networks
 - can reduce 3SAT to exact inference \implies NP-hard
 - equivalent to **counting** 3SAT models \implies #P-complete

1. $A \vee B \vee C$
2. $C \vee D \vee \neg A$
3. $B \vee C \vee \neg D$

approximate inference

Inference by Stochastic Simulation

- Basic idea
 - Draw N samples from a sampling distribution S
 - Compute an approximate posterior probability \hat{P}
 - Show this converges to the true probability P
- Outline
 - Sampling from an empty network
 - Rejection sampling: reject samples disagreeing with evidence
 - Likelihood weighting: use evidence to weight samples
 - Markov chain Monte Carlo (MCMC): sample from a stochastic process whose stationary distribution is the true posterior

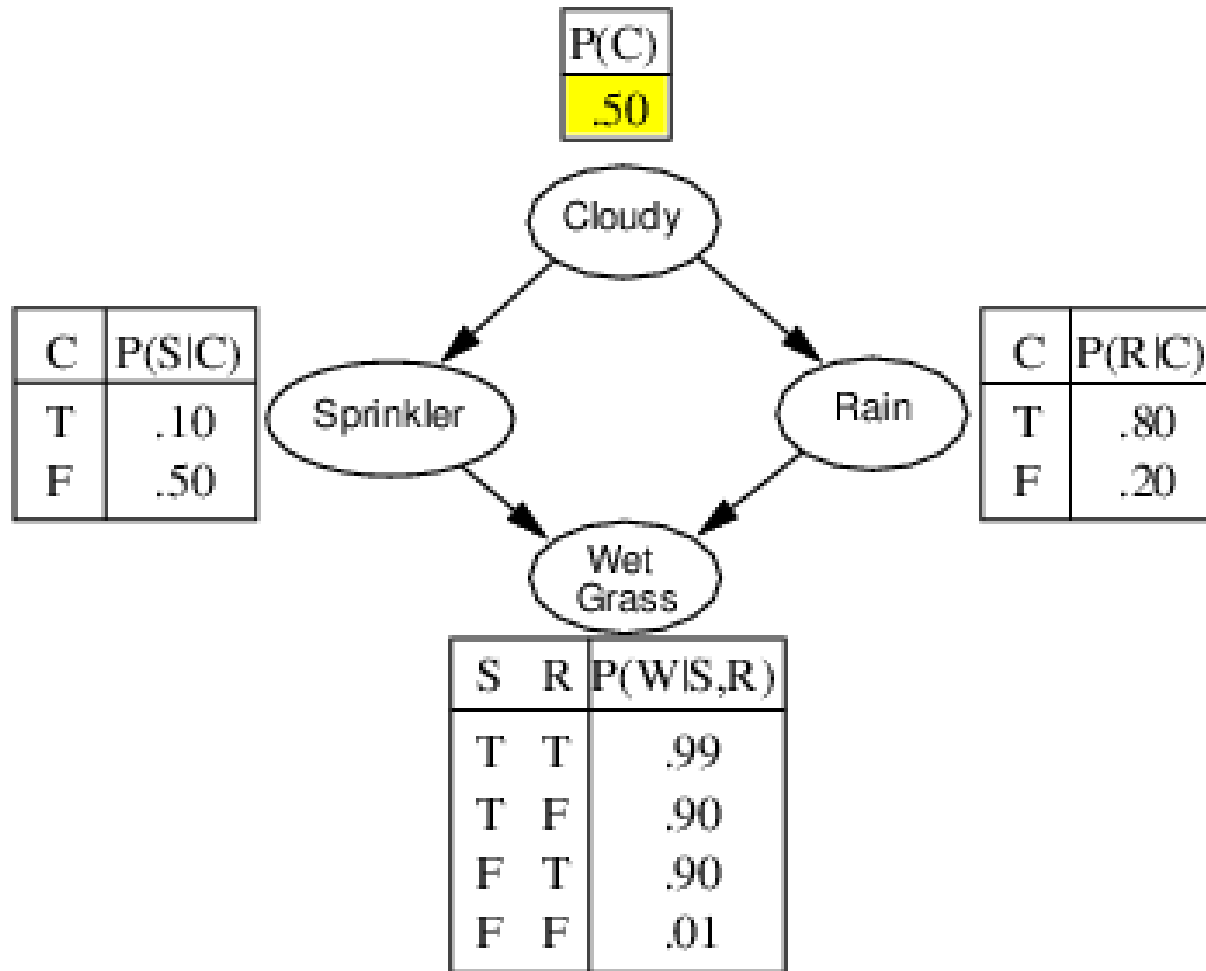

Sampling from an Empty Network

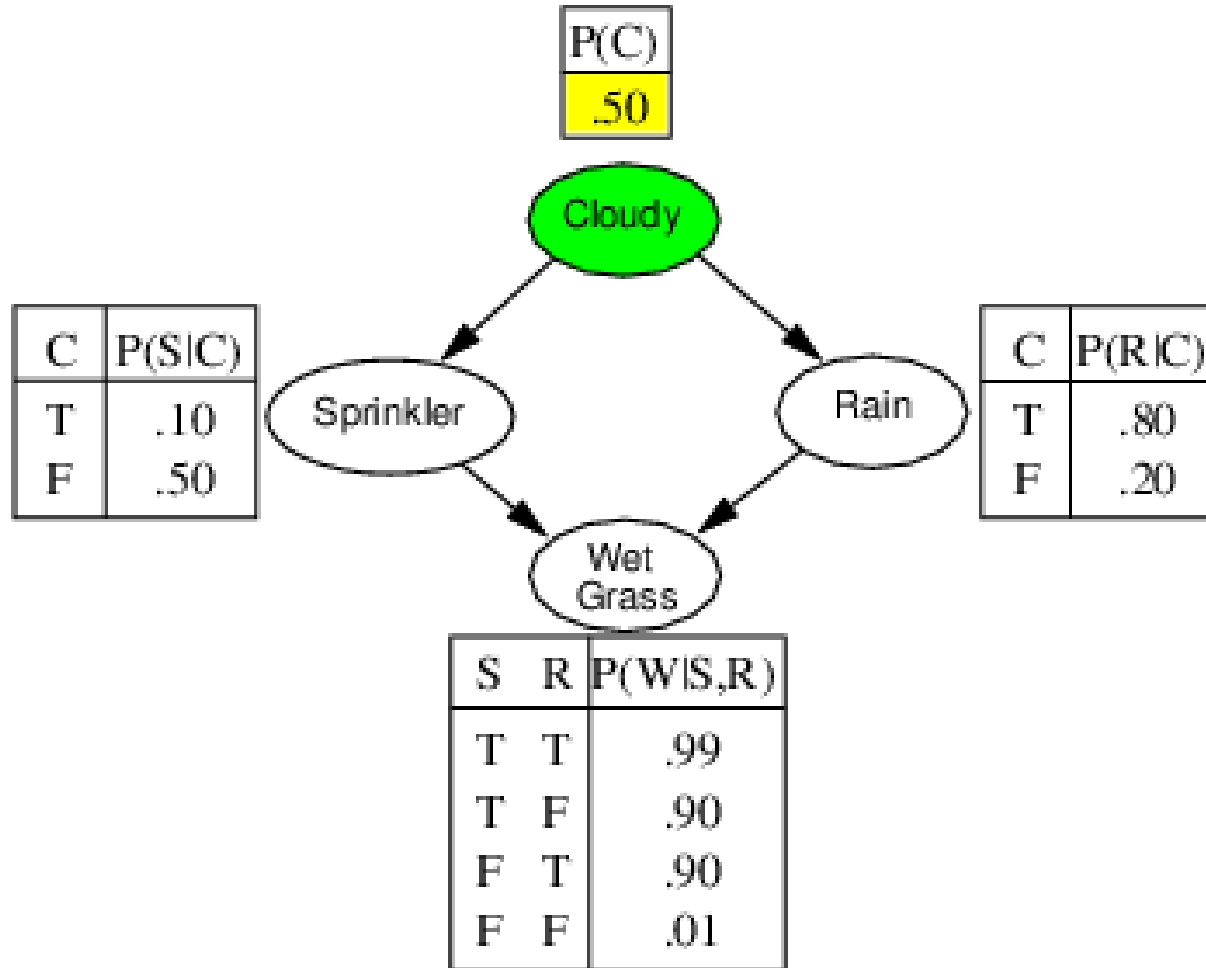

```
function PRIOR-SAMPLE(bn) returns an event sampled from bn  
inputs: bn, a belief network specifying joint distribution  $\mathbf{P}(X_1, \dots, X_n)$   
x  $\leftarrow$  an event with n elements  
for i = 1 to n do  
    xi  $\leftarrow$  a random sample from  $\mathbf{P}(X_i \mid \text{parents}(X_i))$   
    given the values of Parents(Xi) in x  
return x
```

Example

Example

Example

Example

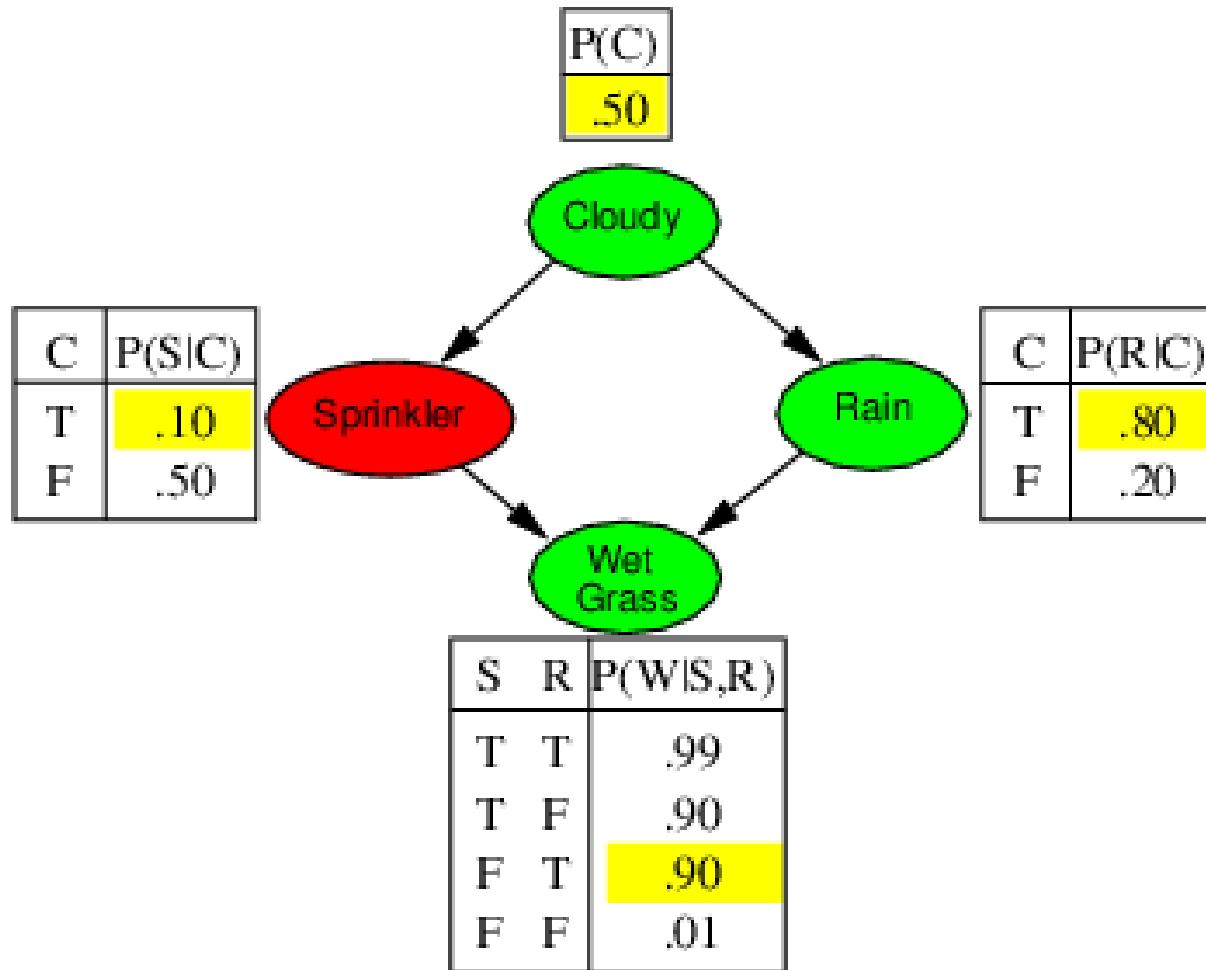

Example

Example

Example

Sampling from an Empty Network

- Probability that PRIORSAMPLE generates a particular event

$$S_{PS}(x_1 \dots x_n) = \prod_{i=1}^n P(x_i | \text{parents}(X_i)) = P(x_1 \dots x_n)$$

i.e., the true prior probability

- E.g., $S_{PS}(t, f, t, t) = 0.5 \times 0.9 \times 0.8 \times 0.9 = 0.324 = P(t, f, t, t)$

- Let $N_{PS}(x_1 \dots x_n)$ be the number of samples generated for event x_1, \dots, x_n

- Then we have
$$\begin{aligned} \lim_{N \rightarrow \infty} \hat{P}(x_1, \dots, x_n) &= \lim_{N \rightarrow \infty} N_{PS}(x_1, \dots, x_n) / N \\ &= S_{PS}(x_1, \dots, x_n) \\ &= P(x_1 \dots x_n) \end{aligned}$$

- That is, estimates derived from PRIORSAMPLE are **consistent**

- Shorthand: $\hat{P}(x_1, \dots, x_n) \approx P(x_1 \dots x_n)$

Rejection Sampling

- $\hat{\mathbf{P}}(X|\mathbf{e})$ estimated from samples agreeing with \mathbf{e}

```
function REJECTION-SAMPLING( $X, \mathbf{e}, bn, N$ ) returns an estimate of  $P(X|\mathbf{e})$   
  local variables:  $\mathbf{N}$ , a vector of counts over  $X$ , initially zero  
  for  $j = 1$  to  $N$  do  
     $\mathbf{x} \leftarrow$  PRIOR-SAMPLE( $bn$ )  
    if  $\mathbf{x}$  is consistent with  $\mathbf{e}$  then  
       $\mathbf{N}[\mathbf{x}] \leftarrow \mathbf{N}[\mathbf{x}] + 1$  where  $\mathbf{x}$  is the value of  $X$  in  $\mathbf{x}$   
  return NORMALIZE( $\mathbf{N}[X]$ )
```

- E.g., estimate $\mathbf{P}(Rain|Sprinkler = true)$ using 100 samples
 27 samples have $Sprinkler = true$
 Of these, 8 have $Rain = true$ and 19 have $Rain = false$
- $\hat{\mathbf{P}}(Rain|Sprinkler = true) = \text{NORMALIZE}(\langle 8, 19 \rangle) = \langle 0.296, 0.704 \rangle$
- Similar to a basic real-world empirical estimation procedure

Analysis of Rejection Sampling

- $\hat{\mathbf{P}}(X|\mathbf{e}) = \alpha \mathbf{N}_{PS}(X, \mathbf{e})$ (algorithm defn.)
= $\mathbf{N}_{PS}(X, \mathbf{e}) / N_{PS}(\mathbf{e})$ (normalized by $N_{PS}(\mathbf{e})$)
 $\approx \mathbf{P}(X, \mathbf{e}) / P(\mathbf{e})$ (property of PRIORSAMPLE)
= $\mathbf{P}(X|\mathbf{e})$ (defn. of conditional probability)
- Hence rejection sampling returns consistent posterior estimates
- Problem: hopelessly expensive if $P(\mathbf{e})$ is small
- $P(\mathbf{e})$ drops off exponentially with number of evidence variables!

Likelihood Weighting

- Idea: fix evidence variables, sample only nonevidence variables, and weight each sample by the likelihood it accords the evidence

```
function LIKELIHOOD-WEIGHTING( $X, \mathbf{e}, bn, N$ ) returns an estimate of  $P(X|\mathbf{e})$   
local variables:  $\mathbf{W}$ , a vector of weighted counts over  $X$ , initially zero  
for  $j = 1$  to  $N$  do  
     $\mathbf{x}, w \leftarrow$  WEIGHTED-SAMPLE( $bn$ )  
     $\mathbf{W}[x] \leftarrow \mathbf{W}[x] + w$  where  $x$  is the value of  $X$  in  $\mathbf{x}$   
return NORMALIZE( $\mathbf{W}[X]$ )
```

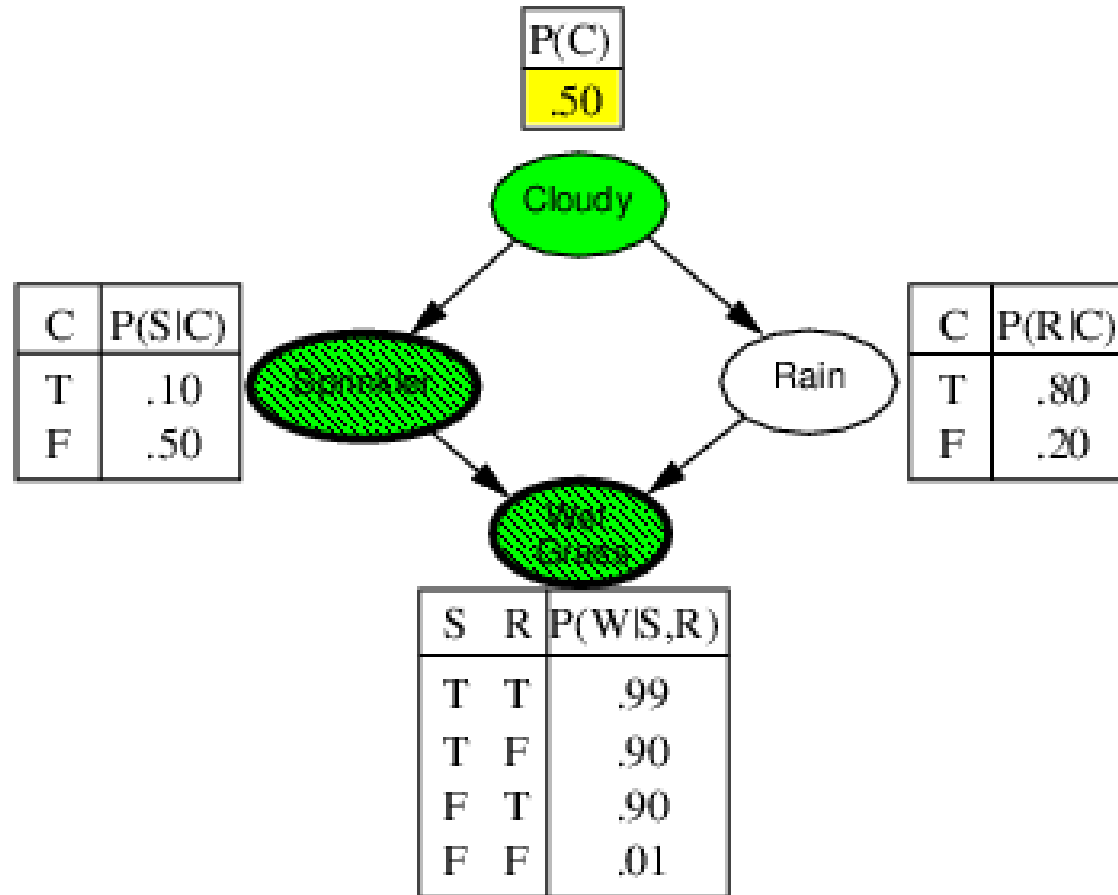

```
function WEIGHTED-SAMPLE( $bn, \mathbf{e}$ ) returns an event and a weight  
 $\mathbf{x} \leftarrow$  an event with  $n$  elements;  $w \leftarrow 1$   
for  $i = 1$  to  $n$  do  
    if  $X_i$  has a value  $x_i$  in  $\mathbf{e}$   
        then  $w \leftarrow w \times P(X_i = x_i \mid \text{parents}(X_i))$   
        else  $x_i \leftarrow$  a random sample from  $\mathbf{P}(X_i \mid \text{parents}(X_i))$   
return  $\mathbf{x}, w$ 
```

Likelihood Weighting Example

$$w = 1.0$$

Likelihood Weighting Example

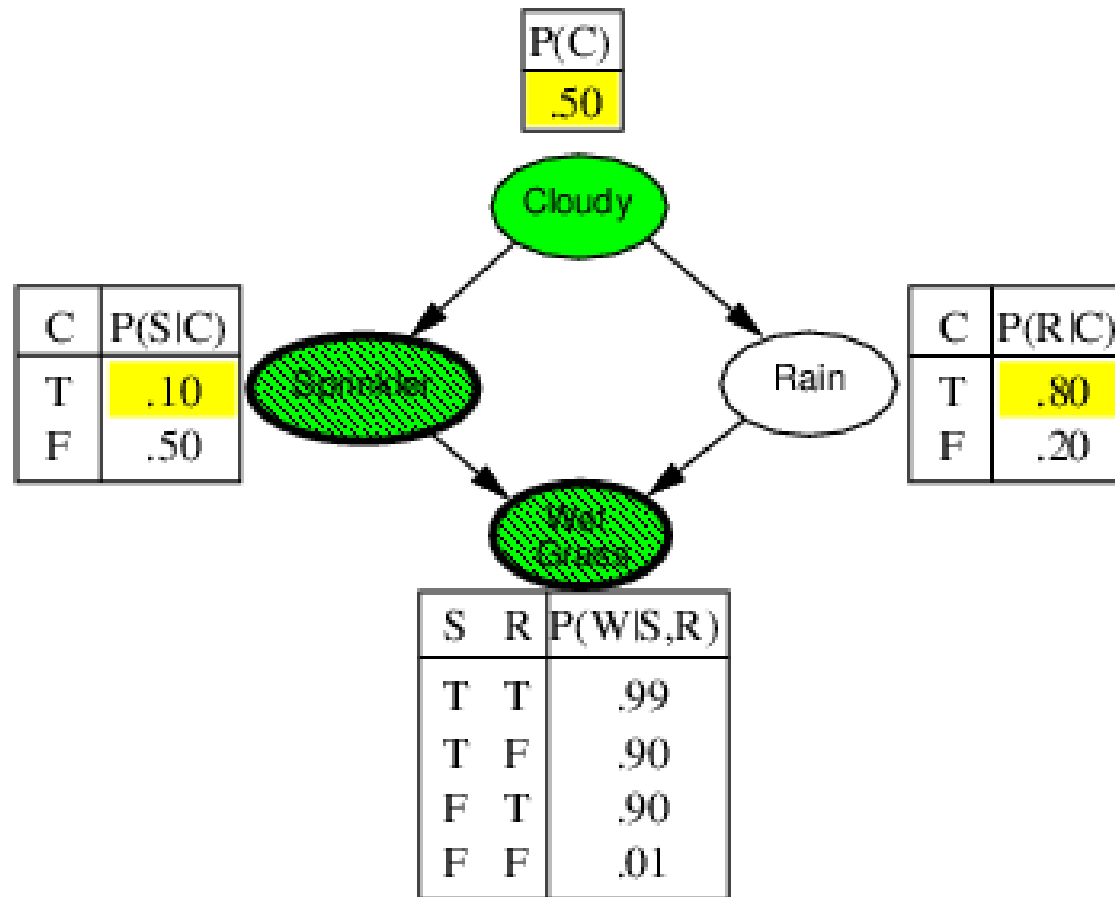

$$w = 1.0$$

Likelihood Weighting Example

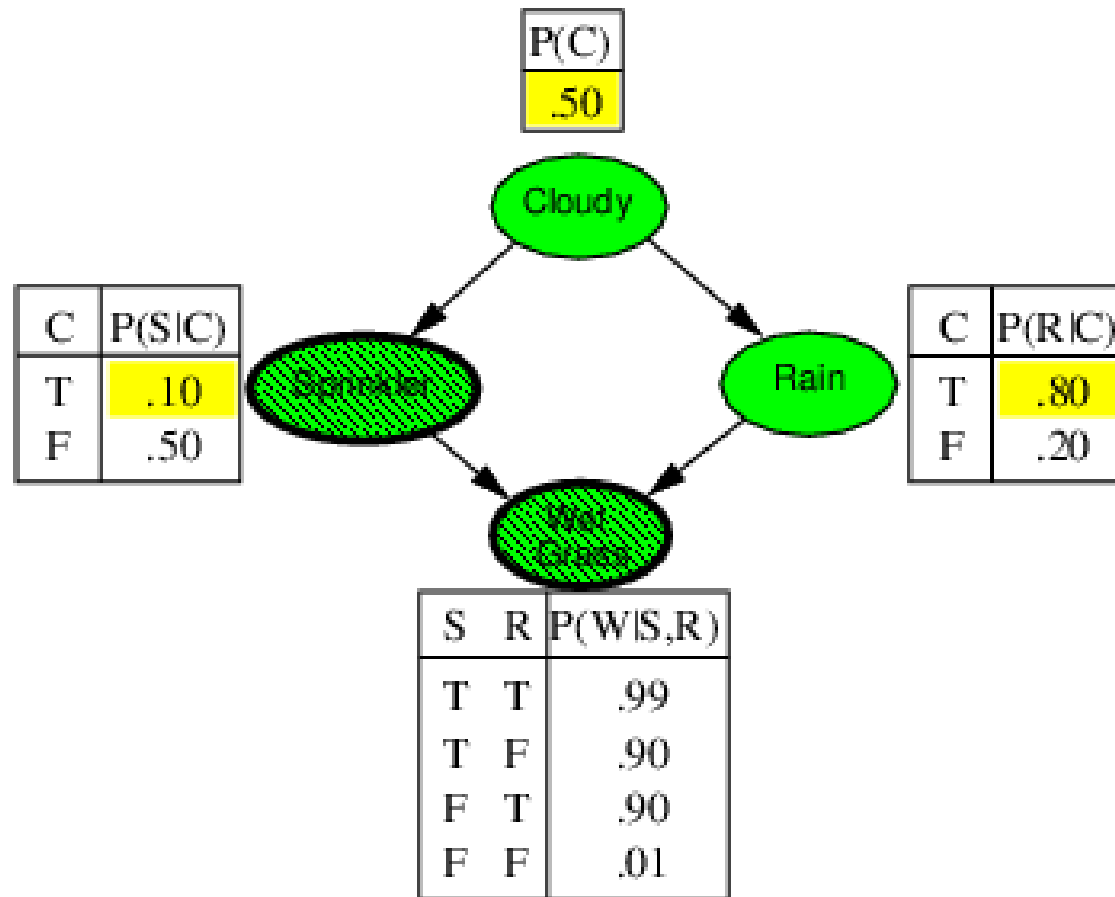

$$w = 1.0$$

Likelihood Weighting Example

$$w = 1.0 \times 0.1$$

Likelihood Weighting Example

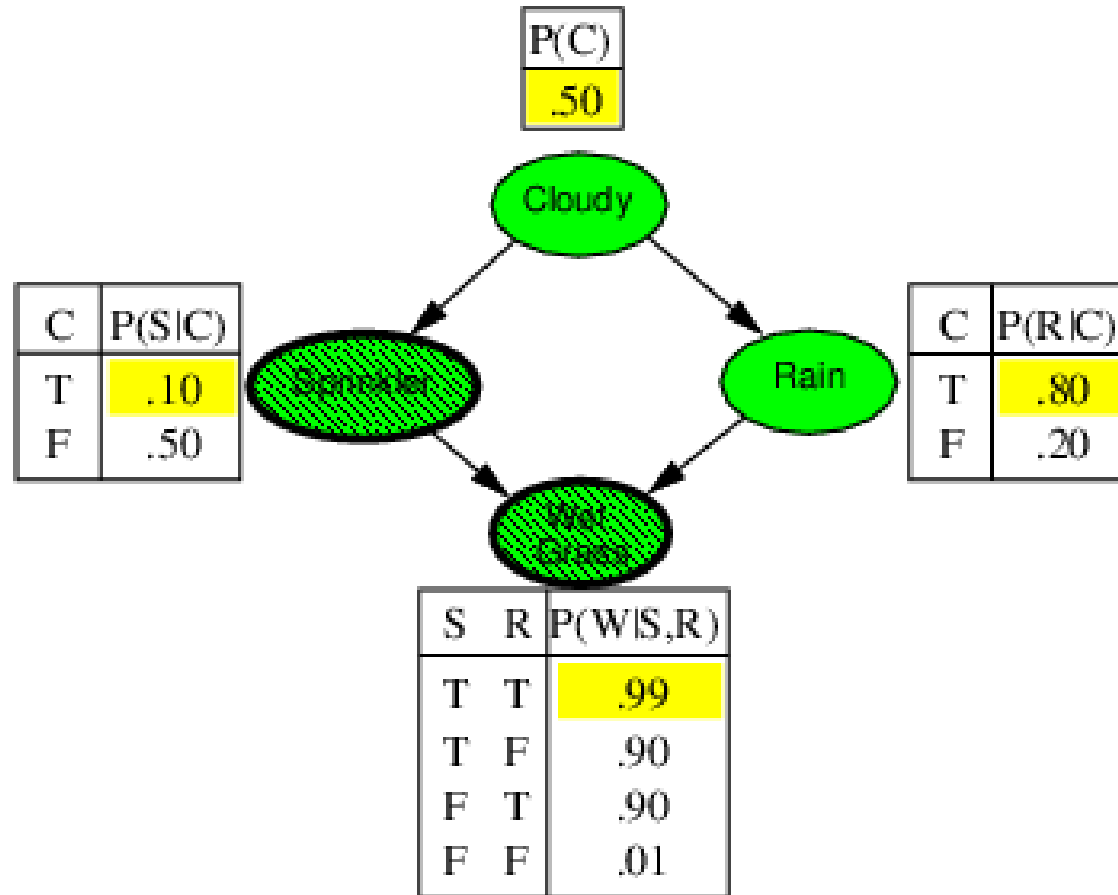

$$w = 1.0 \times 0.1$$

Likelihood Weighting Example

$$w = 1.0 \times 0.1$$

Likelihood Weighting Example

$$w = 1.0 \times 0.1 \times 0.99 = 0.099$$

Likelihood Weighting Analysis

- Sampling probability for WEIGHTEDSAMPLE is

$$S_{WS}(\mathbf{z}, \mathbf{e}) = \prod_{i=1}^l P(z_i | \text{parents}(Z_i))$$

- Note: pays attention to evidence in **ancestors** only
⇒ somewhere “in between” prior and posterior distribution

- Weight for a given sample \mathbf{z}, \mathbf{e} is

$$w(\mathbf{z}, \mathbf{e}) = \prod_{i=1}^m P(e_i | \text{parents}(E_i))$$

- Weighted sampling probability is

$$\begin{aligned} S_{WS}(\mathbf{z}, \mathbf{e}) w(\mathbf{z}, \mathbf{e}) &= \prod_{i=1}^l P(z_i | \text{parents}(Z_i)) \prod_{i=1}^m P(e_i | \text{parents}(E_i)) \\ &= P(\mathbf{z}, \mathbf{e}) \text{ (by standard global semantics of network)} \end{aligned}$$

- Hence likelihood weighting returns consistent estimates but performance still degrades with many evidence variables because a few samples have nearly all the total weight

Approximate Inference using MCMC

- “State” of network = current assignment to all variables
- Generate next state by sampling one variable given Markov blanket
Sample each variable in turn, keeping evidence fixed

```
function MCMC-Ask( $X, \mathbf{e}, bn, N$ ) returns an estimate of  $P(X|\mathbf{e})$   
  local variables:  $\mathbf{N}[X]$ , a vector of counts over  $X$ , initially zero  
                     $\mathbf{Z}$ , the nonevidence variables in  $bn$   
                     $\mathbf{x}$ , the current state of the network, initially copied from  $\mathbf{e}$   
  
  initialize  $\mathbf{x}$  with random values for the variables in  $\mathbf{Y}$   
  for  $j = 1$  to  $N$  do  
    for each  $Z_i$  in  $\mathbf{Z}$  do  
      sample the value of  $Z_i$  in  $\mathbf{x}$  from  $\mathbf{P}(Z_i|mb(Z_i))$   
        given the values of  $MB(Z_i)$  in  $\mathbf{x}$   
       $\mathbf{N}[x] \leftarrow \mathbf{N}[x] + 1$  where  $x$  is the value of  $X$  in  $\mathbf{x}$   
  return NORMALIZE( $\mathbf{N}[X]$ )
```

- Can also choose a variable to sample at random each time

The Markov Chain

- With *Sprinkler = true*, *WetGrass = true*, there are four states:

- Wander about for a while, average what you see

MCMC Example

- Estimate $\mathbf{P}(Rain|Sprinkler = true, WetGrass = true)$
- Sample *Cloudy* or *Rain* given its Markov blanket, repeat.
Count number of times *Rain* is true and false in the samples.
- E.g., visit 100 states
31 have *Rain = true*, 69 have *Rain = false*
- $\hat{\mathbf{P}}(Rain|Sprinkler = true, WetGrass = true)$
 $= \text{NORMALIZE}(\langle 31, 69 \rangle) = \langle 0.31, 0.69 \rangle$
- Theorem: chain approaches **stationary distribution**:
long-run fraction of time spent in each state is exactly
proportional to its posterior probability

Markov Blanket Sampling

- Markov blanket of *Cloudy* is *Sprinkler* and *Rain*
- Markov blanket of *Rain* is *Cloudy*, *Sprinkler*, and *WetGrass*

- Probability given the Markov blanket is calculated as follows:
$$P(x'_i | mb(X_i)) = P(x'_i | parents(X_i)) \prod_{Z_j \in Children(X_i)} P(z_j | parents(Z_j))$$
- Easily implemented in message-passing parallel systems, brains
- Main computational problems
 - difficult to tell if convergence has been achieved
 - can be wasteful if Markov blanket is large:
$$P(X_i | mb(X_i))$$
 won't change much (law of large numbers)

Summary

- Bayes nets provide a natural representation for (causally induced) conditional independence
- Topology + CPTs = compact representation of joint distribution
- Generally easy for (non)experts to construct
- Canonical distributions (e.g., noisy-OR) = compact representation of CPTs
- Continuous variables \implies parameterized distributions (e.g., linear Gaussian)
- Exact inference by variable elimination
 - polytime on polytrees, NP-hard on general graphs
 - space = time, very sensitive to topology
- Approximate inference by LW, MCMC
 - LW does poorly when there is lots of (downstream) evidence
 - LW, MCMC generally insensitive to topology
 - Convergence can be very slow with probabilities close to 1 or 0
 - Can handle arbitrary combinations of discrete and continuous variables
