Inference in First-Order Logic

Philipp Koehn

12 March 2019

A Brief History of Reasoning

450B.C.	Stoics	propositional logic, inference (maybe)
322B.C.	Aristotle	"syllogisms" (inference rules), quantifiers
1565	Cardano	probability theory (propositional logic + uncertainty)
1847	Boole	propositional logic (again)
1879	Frege	first-order logic
1922	Wittgenstein	proof by truth tables
1930	Gödel	∃ complete algorithm for FOL
1930	Herbrand	complete algorithm for FOL (reduce to propositional)
1931	Gödel	¬∃ complete algorithm for arithmetic
1960	Davis/Putnam	"practical" algorithm for propositional logic
1965	Robinson	"practical" algorithm for FOL—resolution

The Story So Far

- Propositional logic
- Subset of propositional logic: horn clauses
- Inference algorithms
 - forward chaining
 - backward chaining
 - resolution (for full propositional logic)
- First order logic (FOL)
 - variables
 - functions
 - quantifiers
 - etc.
- Today: inference for first order logic

Outline

- Reducing first-order inference to propositional inference
- Unification
- Generalized Modus Ponens
- Forward and backward chaining
- Logic programming
- Resolution

reduction to propositional inference

Universal Instantiation

• Every instantiation of a universally quantified sentence is entailed by it:

$$\frac{\forall \ v \ \alpha}{\mathsf{SUBST}(\{v/g\},\alpha)}$$

for any variable v and ground term g

• E.g., $\forall x \ King(x) \land Greedy(x) \Longrightarrow Evil(x)$ yields

```
King(John) \wedge Greedy(John) \Longrightarrow Evil(John)

King(Richard) \wedge Greedy(Richard) \Longrightarrow Evil(Richard)

King(Father(John)) \wedge Greedy(Father(John)) \Longrightarrow Evil(Father(John))

:
```

Existential Instantiation

• For any sentence α , variable v, and constant symbol k that does not appear elsewhere in the knowledge base:

$$\frac{\exists v \ \alpha}{\mathsf{SUBST}(\{v/k\},\alpha)} \blacksquare$$

• E.g., $\exists x \ Crown(x) \land OnHead(x, John)$ yields

$$Crown(C_1) \wedge OnHead(C_1, John)$$

provided C_1 is a new constant symbol, called a Skolem constant

Instantiation

- Universal Instantiation
 - can be applied several times to add new sentences
 - the new KB is logically equivalent to the old

- Existential Instantiation
 - can be applied once to **replace** the existential sentence
 - the new KB is **not** equivalent to the old
 - but is satisfiable iff the old KB was satisfiable

Reduction to Propositional Inference

• Suppose the KB contains just the following:

```
\forall x \ King(x) \land Greedy(x) \Longrightarrow Evil(x)
King(John)
Greedy(John)
Brother(Richard, John)
```

• Instantiating the universal sentence in **all possible** ways, we have

```
King(John) \wedge Greedy(John) \Longrightarrow Evil(John)

King(Richard) \wedge Greedy(Richard) \Longrightarrow Evil(Richard)

King(John)

Greedy(John)

Brother(Richard, John)
```

• The new KB is propositionalized: proposition symbols are

King(John), Greedy(John), Evil(John), Brother(Richard, John), etc.

Reduction to Propositional Inference

- Claim: a ground sentence* is entailed by new KB iff entailed by original KB
- Claim: every FOL KB can be propositionalized so as to preserve entailment
- Idea: propositionalize KB and query, apply resolution, return result
- Problem: with function symbols, there are infinitely many ground terms, e.g., Father(Father(John))
- Theorem: Herbrand (1930). If a sentence α is entailed by an FOL KB, it is entailed by a **finite** subset of the propositional KB
- Idea: For n=0 to ∞ do create a propositional KB by instantiating with depth-n terms see if α is entailed by this KB
- Problem: works if α is entailed, loops if α is not entailed
- Theorem: Turing (1936), Church (1936), entailment in FOL is semidecidable

Practical Problems with Propositionalization 10

Propositionalization seems to generate lots of irrelevant sentences.

```
• E.g., from
                           \forall x \ King(x) \land Greedy(x) \Longrightarrow Evil(x)
                           King(John)
                           \forall y \ Greedy(y)
                           Brother(Richard, John)
```

it seems obvious that Evil(John), but propositionalization produces lots of facts such as Greedy(Richard) that are irrelevant

- With p k-ary predicates and n constants, there are $p \cdot n^k$ instantiations
- With function symbols, it gets nuch much worse!

Plan

- We have the inference rule
 - $\forall x \ King(x) \land Greedy(x) \Longrightarrow Evil(x)$
- We have facts that (partially) match the precondition
 - King(John)
 - $\forall y \ Greedy(y)$
- We need to match them up with substitutions: $\theta = \{x/John, y/John\}$ works
 - unification
 - generalized modus ponens

p	$\mid q$	$\mid heta \mid$
Knows(John, x)	[Knows(John,Jane)]	
Knows(John, x)	$\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ $	
Knows(John, x)	Knows(y, Mother(y))	
Knows(John,x)	Knows(x, Mary)	

p	$\mid q$	$\mid heta \mid$
Knows(John, x)	[Knows(John,Jane)]	$\{x/Jane\}$
Knows(John, x)	Knows(y, Mary)	
Knows(John, x)	Knows(y, Mother(y))	
Knows(John, x)	$\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ $	

p	$\mid q$	heta
Knows(John, x)	Knows(John, Jane)	$\{x/Jane\}$
Knows(John, x)	Knows(y, Mary)	$\{x/Mary, y/John\}$
Knows(John, x)	Knows(y, Mother(y))	
Knows(John, x)	Knows(x, Mary)	

p	$\mid q$	$\mid heta \mid$
Knows(John, x)	Knows(John, Jane)	$\{x/Jane\}$
Knows(John, x)	Knows(y, Mary)	$\{x/Mary, y/John\}$
Knows(John, x)	Knows(y, Mother(y))	$\{y/John, x/Mother(John)\}$
Knows(John, x)	Knows(x, Mary)	

• UNIFY(α, β) = θ if $\alpha\theta = \beta\theta$

p	$\mid q$	$\mid heta \mid$
Knows(John, x)	[Knows(John,Jane)]	$\{x/Jane\}$
Knows(John, x)	Knows(y, Mary)	$\{x/Mary, y/John\}$
Knows(John, x)	Knows(y, Mother(y))	$\{y/John, x/Mother(John)\}$
Knows(John,x)	Knows(x, Mary)	$\mid fail \blacksquare$

• Standardizing apart eliminates overlap of variables, e.g., $Knows(z_{17}, Mary)$

$$Knows(John, x) \mid Knows(z_{17}, Mary) \mid \{z_{17}/John, x/Mary\}$$

generalized modus ponens

Generalized Modus Ponens

- Generalized modus ponens used with KB of **definite clauses** (exactly one positive literal)
- All variables assumed universally quantified

$$\frac{p_1', p_2', \dots, p_n', (p_1 \land p_2 \land \dots \land p_n \Rightarrow q)}{q\theta} \quad \text{where } p_i'\theta = p_i\theta \text{ for all } i$$

- Rule: $King(x) \land Greedy(x) \Longrightarrow Evil(x)$
- Precondition of rule: p_1 is King(x) p_2 is Greedy(x)
- Implication: $q ext{ is } Evil(x)$
- Facts: p_1' is King(John) p_2' is Greedy(y)
- Substitution: θ is $\{x/John, y/John\}$
- \Rightarrow Result of modus ponens: $q\theta$ is Evil(John)

forward chaining

Example Knowledge

• The law says that it is a crime for an American to sell weapons to hostile nations. The country Nono, an enemy of America, has some missiles, and all of its missiles were sold to it by Colonel West, who is American.

Prove that Col. West is a criminal

Example Knowledge Base

- ... it is a crime for an American to sell weapons to hostile nations:
 - $American(x) \land Weapon(y) \land Sells(x, y, z) \land Hostile(z) \implies Criminal(x)$
- Nono . . . has some missiles, i.e., $\exists x \ Owns(Nono, x) \land Missile(x)$: $Owns(Nono, M_1)$ and $Missile(M_1)$
- ... all of its missiles were sold to it by Colonel Westl $\forall x \; Missile(x) \land Owns(Nono, x) \Longrightarrow Sells(West, x, Nono)$
- Missiles are weapons: $Missile(x) \Rightarrow Weapon(x)$
- An enemy of America counts as "hostile": $Enemy(x, America) \implies Hostile(x)$
- West, who is American ... American(West)
- The country Nono, an enemy of America ... Enemy(Nono, America)

Forward Chaining Proof

American(West)

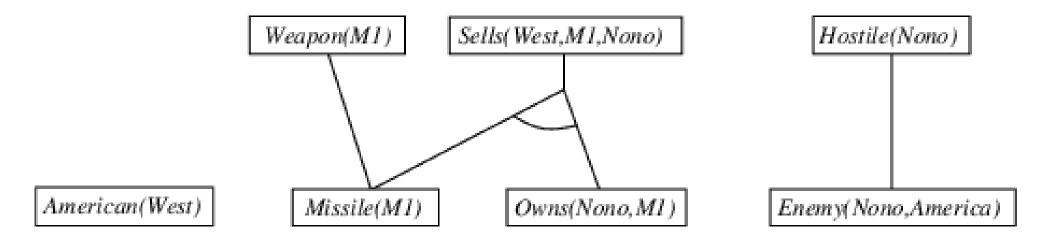

Missile(M1)

Owns(Nono, M1)

Enemy(Nono,America)

Forward Chaining Proof

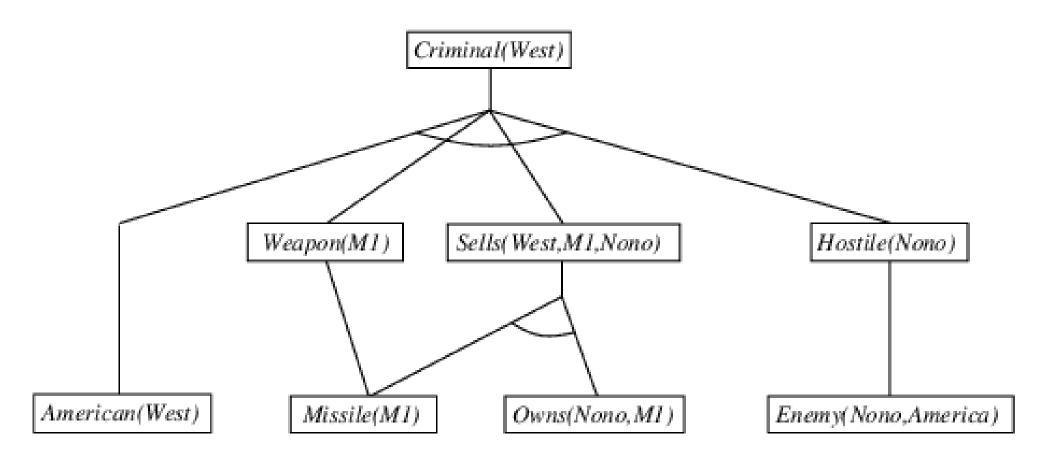

(Note: $\forall x \; Missile(x) \land Owns(Nono, x) \implies Sells(West, x, Nono)$)

Forward Chaining Proof

(Note: $American(x) \land Weapon(y) \land Sells(x, y, z) \land Hostile(z) \implies Criminal(x)$)

Properties of Forward Chaining

- Sound and complete for first-order definite clauses (proof similar to propositional proof)
- **Datalog** (1977) = first-order definite clauses + no functions (e.g., crime example) Forward chaining terminates for Datalog in poly iterations: at most $p \cdot n^k$ literals
- May not terminate in general if α is not entailed
- This is unavoidable: entailment with definite clauses is semidecidable

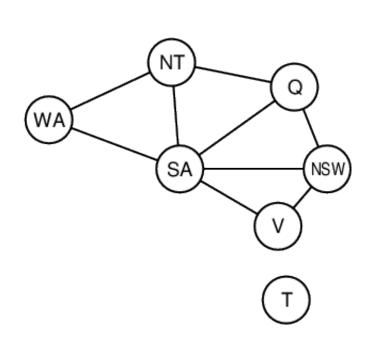

Efficiency of Forward Chaining

- Simple observation: no need to match a rule on iteration k if a premise wasn't added on iteration k-1
 - ⇒ match each rule whose premise contains a newly added literal
- Matching itself can be expensive
- Database indexing allows O(1) retrieval of known facts e.g., query Missile(x) retrieves $Missile(M_1)$
- Matching conjunctive premises against known facts is NP-hard
- Forward chaining is widely used in deductive databases

Hard Matching Example

```
Diff(wa, nt) \wedge Diff(wa, sa) \wedge \\ Diff(nt, q) Diff(nt, sa) \wedge \\ Diff(q, nsw) \wedge Diff(q, sa) \wedge \\ Diff(nsw, v) \wedge Diff(nsw, sa) \wedge \\ Diff(v, sa) \Longrightarrow Colorable() \\ Diff(Red, Blue) \quad Diff(Red, Green) \\ Diff(Green, Red) \quad Diff(Green, Blue) \\ Diff(Blue, Red) \quad Diff(Blue, Green)
```

- *Colorable*() is inferred iff the constraint satisfaction problem has a solution
- CSPs include 3SAT as a special case, hence matching is NP-hard

Forward Chaining Algorithm

```
function FOL-FC-Ask(KB, \alpha) returns a substitution or false
   repeat until new is empty
       new ← Ø
       for each sentence r in KB do
            (p_1 \land \ldots \land p_n \implies q) \leftarrow \mathsf{STANDARDIZE} - \mathsf{APART}(r)
            for each \theta such that (p_1 \wedge \ldots \wedge p_n)\theta = (p'_1 \wedge \ldots \wedge p'_n)\theta
                          for some p'_1, \ldots, p'_n in KB
                 q' \leftarrow \mathsf{SUBST}(\theta, q)
                 if q' is not a renaming of a sentence already in KB or new then do
                     add q' to new
                     \phi \leftarrow \mathsf{UNIFY}(q', \alpha)
                     if \phi is not fail then return \phi
       add new to KB
   return false
```

backward chaining

Backward Chaining

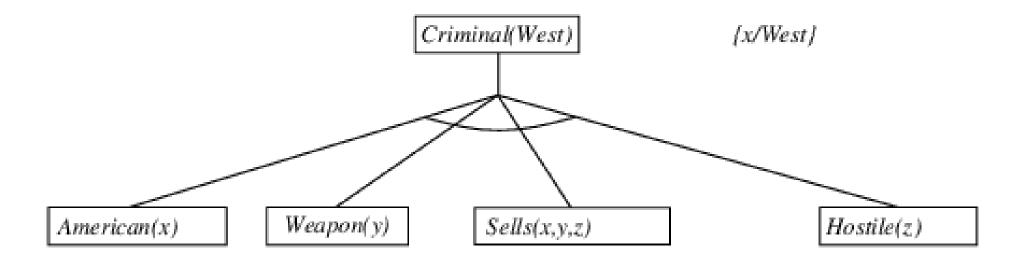

• Start with query

- Check if it can be derived by given rules and facts
 - apply rules that infer the query
 - recurse over pre-conditions

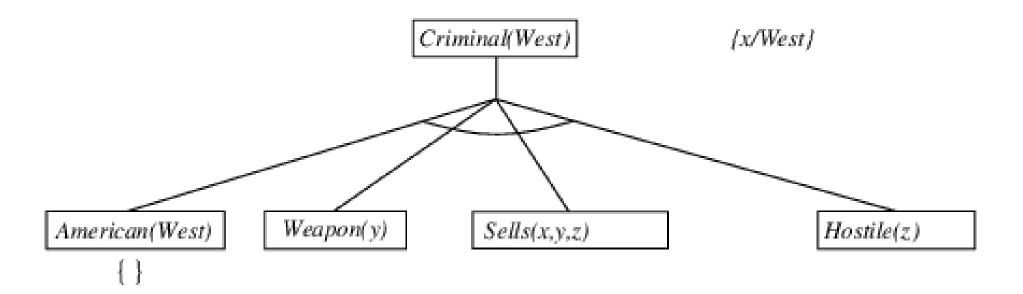

Criminal(West)

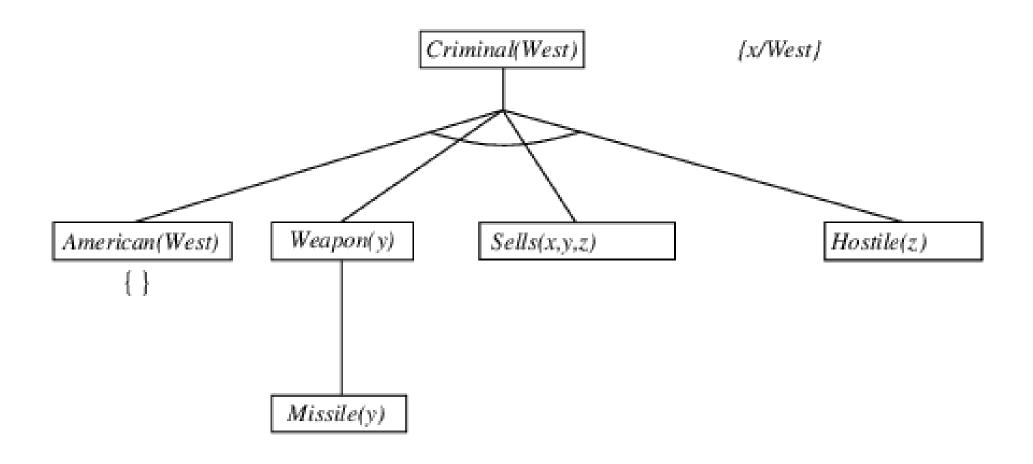

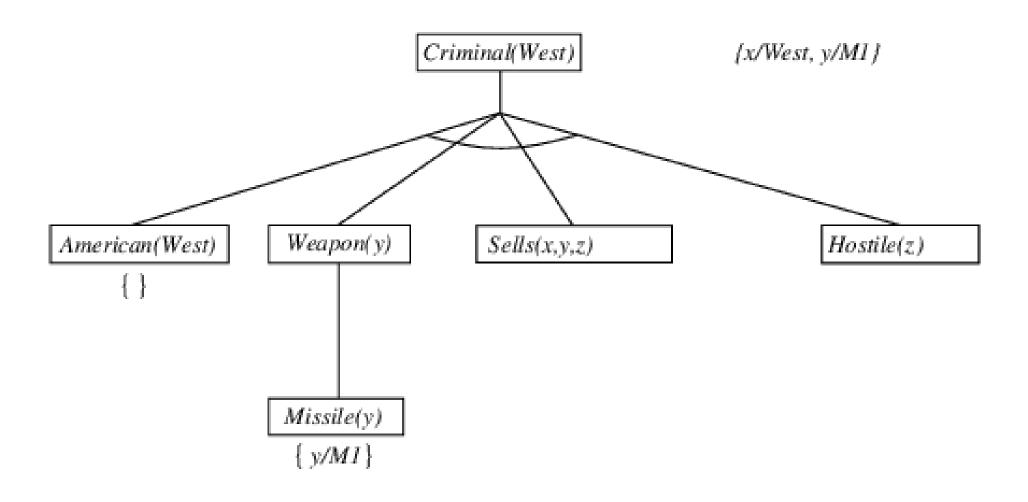

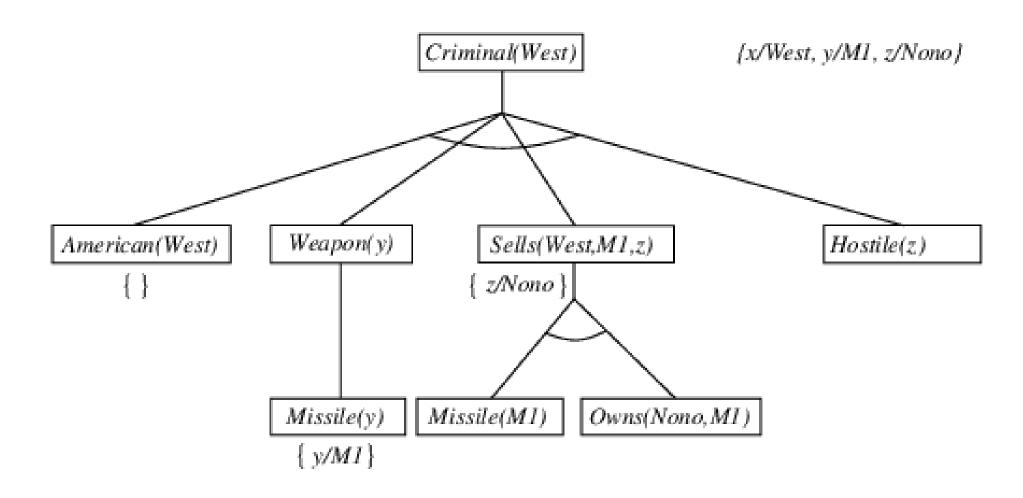

Backward Chaining Example

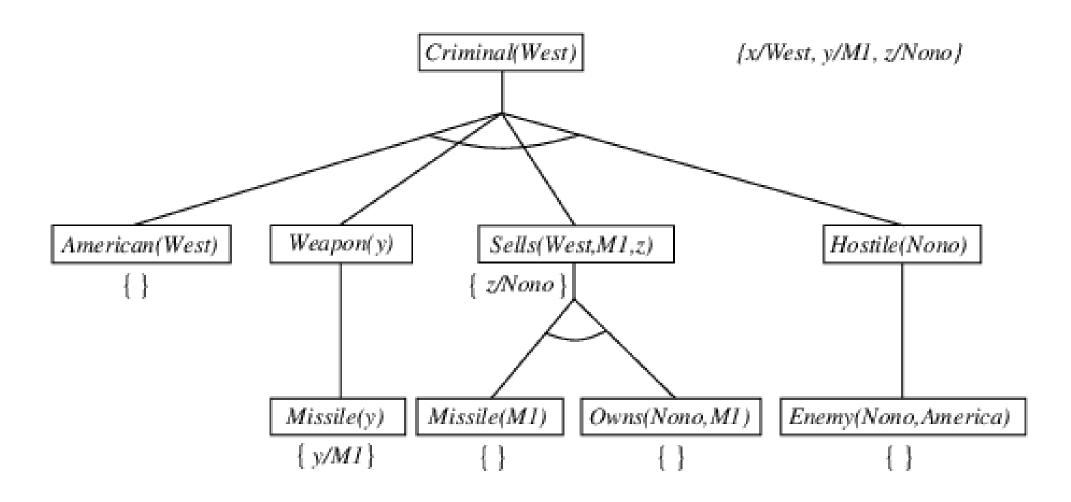

Backward Chaining Example

Backward Chaining Example

Properties of Backward Chaining

- Depth-first recursive proof search: space is linear in size of proof
- Incomplete due to infinite loops
 - ⇒ fix by checking current goal against every goal on stack
- Inefficient due to repeated subgoals (both success and failure)
 - ⇒ fix using caching of previous results (extra space!)
- Widely used (without improvements!) for logic programming

Backward Chaining Algorithm

```
function FOL-BC-Ask(KB, goals, \theta) returns a set of substitutions
  inputs: KB, a knowledge base
            goals, a list of conjuncts forming a query (\theta already applied)
            \theta, the current substitution, initially the empty substitution \varnothing
  local variables: answers, a set of substitutions, initially empty
  if goals is empty then return \{\theta\}
   q' \leftarrow \mathsf{SUBST}(\theta, \mathsf{FIRST}(goals))
  for each sentence r in KB
          where STANDARDIZE-APART(r) = (p_1 \land ... \land p_n \Rightarrow q)
           and \theta' \leftarrow \mathsf{UNIFY}(q, q') succeeds
       new\_goals \leftarrow [p_1, \dots, p_n | REST(goals)]
       answers ← FOL-BC-Ask(KB, new\_goals, Compose(\theta', \theta)) ∪ answers
  return answers
```

logic programming

Logic Programming

• Sound bite: computation as inference on logical KBs

	Logic programming	Ordinary programming
1.	Identify problem	Identify problem •
2.	Assemble information	Assemble information •
3.	Tea break	Figure out solution
4.	Encode information in KB	Program solution
5.	Encode problem instance as facts	Encode problem instance as data
6.	Ask queries	Apply program to data
7.	Find false facts	Debug procedural errors

• Should be easier to debug Capital(NewYork, US) than x := x + 2!

Prolog

- Basis: backward chaining with Horn clauses + bells & whistles
- Widely used in Europe, Japan (basis of 5th Generation project)
- Compilation techniques ⇒ approaching a billion logical inferences per second
- Program = set of clauses = head :- literal₁, ... literal_n.

```
\label{eq:criminal} \begin{split} & \text{criminal}(X) := \text{american}(X), \ \text{weapon}(Y), \ \text{sells}(X,Y,Z), \ \text{hostile}(Z). \\ & \text{missile}(M_1). \\ & \text{owns}(\text{Nono},M_1). \\ & \text{sells}(\text{West},X,\text{Nono}) := \text{missile}(X), \ \text{owns}(\text{Nono},X). \\ & \text{weapon}(X) := \text{missile}(X). \\ & \text{hostile}(X) := \text{enemy}(X,\text{America}). \\ & \text{American}(\text{West}). \\ & \text{Enemy}(\text{Nono},\text{America}). \end{split}
```

Prolog Systems

- Depth-first, left-to-right backward chaining
- Built-in predicates for arithmetic etc., e.g., X is Y*Z+3
- Closed-world assumption ("negation as failure")
 e.g., given alive(X): not dead(X).
 alive(joe) succeeds if dead(joe) fails

resolution

Resolution: Brief Summary

• Full first-order version:

$$\frac{\ell_1 \vee \dots \vee \ell_k, \quad m_1 \vee \dots \vee m_n}{(\ell_1 \vee \dots \vee \ell_{i-1} \vee \ell_{i+1} \vee \dots \vee \ell_k \vee m_1 \vee \dots \vee m_{j-1} \vee m_{j+1} \vee \dots \vee m_n)\theta}$$

where UNIFY $(\ell_i, \neg m_j) = \theta$.

• For example,

$$\neg Rich(x) \lor Unhappy(x)$$

$$Rich(Ken)$$

$$Unhappy(Ken)$$

with $\theta = \{x/Ken\}$

• Apply resolution steps to $CNF(KB \land \neg \alpha)$; complete for FOL

Conversion to CNF

Everyone who loves all animals is loved by someone:

$$\forall x \ [\forall y \ Animal(y) \Longrightarrow Loves(x,y)] \Longrightarrow [\exists y \ Loves(y,x)]$$

1. Eliminate biconditionals and implications

$$\forall x \ [\neg \forall y \ \neg Animal(y) \lor Loves(x,y)] \lor [\exists y \ Loves(y,x)]$$

2. Move \neg inwards: $\neg \forall x, p \equiv \exists x \neg p$, $\neg \exists x, p \equiv \forall x \neg p$:

$$\forall x \ [\exists y \ \neg(\neg Animal(y) \lor Loves(x,y))] \lor [\exists y \ Loves(y,x)] \\ \forall x \ [\exists y \ \neg\neg Animal(y) \land \neg Loves(x,y)] \lor [\exists y \ Loves(y,x)] \\ \forall x \ [\exists y \ Animal(y) \land \neg Loves(x,y)] \lor [\exists y \ Loves(y,x)]$$

Conversion to CNF

3. Standardize variables: each quantifier should use a different one

$$\forall x \ [\exists y \ Animal(y) \land \neg Loves(x,y)] \lor [\exists z \ Loves(z,x)]$$

4. Skolemize: a more general form of existential instantiation. Each existential variable is replaced by a Skolem function of the enclosing universally quantified variables:

$$\forall x \ [Animal(F(x)) \land \neg Loves(x, F(x))] \lor Loves(G(x), x)$$

5. Drop universal quantifiers:

$$[Animal(F(x)) \land \neg Loves(x, F(x))] \lor Loves(G(x), x)$$

6. Distribute ∧ over ∨:

$$[Animal(F(x)) \lor Loves(G(x), x)] \land [\neg Loves(x, F(x)) \lor Loves(G(x), x)]$$

Our Previous Example

• Rules

- $American(x) \land Weapon(y) \land Sells(x, y, z) \land Hostile(z) \Longrightarrow Criminal(x)$
- $Missile(M_1)$ and $Owns(Nono, M_1)$
- $\forall x \ Missile(x) \land Owns(Nono, x) \Longrightarrow Sells(West, x, Nono)$
- $Missile(x) \Rightarrow Weapon(x)$
- $Enemy(x, America) \implies Hostile(x)$
- American(West)
- Enemy(Nono, America)

Converted to CNF

- $-\neg American(x) \lor \neg Weapon(y) \lor \neg Sells(x,y,z) \lor \neg Hostile(z) \lor Criminal(x)$
- $Missile(M_1)$ and $Owns(Nono, M_1)$
- $\neg Missile(x) \lor \neg Owns(Nono, x) \lor Sells(West, x, Nono)$
- $\neg Missile(x) \lor Weapon(x)$
- $-\neg Enemy(x, America) \lor Hostile(x)$
- American(West)
- Enemy(Nono, America)
- Query: $\neg Criminal(West)$

Resolution Proof
