Finding point-pairs

• Given an $a$, find a corresponding $b$ on the surface.
• One approach would be to search every possible triangle or surface point and then take the closest point.
• The key is to find a more efficient way to do this

Suppose surface is represented by dense cloud of points
Find Closest Point from Dense Cloud

- Basic approach is to divide space into regions. Suppose that we have one point $b_k^*$ that is a possible match for a point $a_k$. The distance $\Delta^*=||b_k^* - a_k||$ obviously acts as an upper bound on the distance of the closest point to the surface.
- Given a region $R$ containing many possible points $b_j$, if we can compute a lower bound $\Delta_L$ on the distance from $a$ to any point in $R$, then we need only consider points inside $R$ if $\Delta_L < \Delta^*$.

Given a match, is there anything closer?
Divide cloud into cells

Can exclude everything outside circle
Find Closest Point from Dense Cloud

- There are many ways to implement this idea
  - Simply partitioning space into many buckets
  - Octrees, KD trees, covariance trees, etc.

Approaches to closest triangle finding

1. (Simplest) Construct linear list of triangles and search sequentially for closest triangle to each point.
2. (Only slightly harder) Construct bounding spheres or bounding boxes around each triangle and use these to reduce the number of careful checks required.
3. (Faster if have lots of points) Construct hierarchical data structure to speed search.
4. (Better but harder) Rotate each level of the tree to align with data.
FindClosestPoint(a,[p,q,r])
Many approaches. One is to solve the system
\[ a - p = \lambda(q - p) + \mu(r - p) \]
in a least squares sense for \( \lambda \) and \( \mu \). Then compute
\[ c = p + \lambda(q - p) + \mu(r - p) \]
If \( \lambda \geq 0, \mu \geq 0, \lambda + \mu \leq 1 \), then \( c \) lies within the triangle
and is the closest point. Otherwise, you need to find a point on the border of the triangle

Hint: For efficiency, work out the least squares problem explicitly for \( \lambda, \mu \)

Simple Search with Bounding Boxes

// Triangle i has corners \([\hat{p}_i, \hat{q}_i, \hat{r}_i]\)
// Bounding box lower = \(L_i = [L_{x_i}, L_{y_i}, L_{z_i}]^T\); upper = \(\bar{U}_i = [U_{x_i}, U_{y_i}, U_{z_i}]^T\)

bound = \(\infty\)
for \(i = 1\) to \(N\) do
{ if \((L_{x_i} - \text{bound} \leq a_x \leq U_{x_i} + \text{bound})\) and \((L_{y_i} - \text{bound} \leq a_y \leq U_{y_i} + \text{bound})\) and \((L_{z_i} - \text{bound} \leq a_z \leq U_{z_i} + \text{bound})\) then
    { \(\hat{h} = \text{FindClosestPoint}(\hat{a}, [\hat{p}_i, \hat{q}_i, \hat{r}_i]);\) if \(\|\hat{h} - \hat{a}\| < \text{bound}\) then
        { \(c = \hat{h}; \text{ bound } = \|\hat{h} - \hat{a}\|;\) }
    }
};
Simple Search with Bounding Spheres

```c
// Triangle i has corners [\(\tilde{p}_i, \tilde{q}_i, \tilde{r}_i\)]
// Surrounding sphere i has radius \(\rho_i\), center \(\tilde{q}_i\)
bound = \(\infty\);
for i=1 to N do
{ if \(\|\tilde{q}_i - \tilde{a}\| - \rho_i \leq \text{bound}\) then
    { \(\tilde{h}\) = \text{FindClosestPoint}(\(\tilde{a}, [\tilde{p}_i, \tilde{q}_i, \tilde{r}_i]\));
        if \(\|\tilde{h} - \tilde{a}\| < \text{bound}\) then
            { \(\tilde{c}\) = \(\tilde{h}\); bound = \(\|\tilde{h} - \tilde{a}\|\););
        };
    }
};
```

Bounding Sphere

Suppose you have a point \(\tilde{p}\) and are trying to find the closest triangle \((\tilde{a}_k, \tilde{b}_k, \tilde{c}_k)\) to \(\tilde{p}\). If you have already found a triangle \((\tilde{a}_j, \tilde{b}_j, \tilde{c}_j)\) with a point \(\tilde{r}_j\) on it, when do you need to check carefully for some triangle \(k\)?

Answer: if \(\tilde{q}_k\) is the center of a sphere of radius \(\rho_k\) enclosing \((\tilde{a}_k, \tilde{b}_k, \tilde{c}_k)\), then you only need to check carefully if
\[
\|\tilde{p} - \tilde{q}_k\| - \rho_k < \|\tilde{p} - \tilde{r}_j\|.
\]
Bounding Sphere

Assume edge \((\vec{a}, \vec{b})\) is the longest.
Then the center \(\vec{q}\) of the sphere will obey
\[
(\vec{b} - \vec{q}) \cdot (\vec{b} - \vec{q}) = (\vec{a} - \vec{q}) \cdot (\vec{a} - \vec{q})
\]
\[
(\vec{c} - \vec{q}) \cdot (\vec{c} - \vec{q}) \leq (\vec{a} - \vec{q}) \cdot (\vec{a} - \vec{q})
\]
\[
(\vec{b} - \vec{a}) \times (\vec{c} - \vec{a}) \cdot (\vec{q} - \vec{a}) = 0
\]

Simple approach: Try \(\vec{q} = (\vec{a} + \vec{b}) / 2\).
If inequality holds, then done.
Else solve the system to get \(\vec{q}\) (next page).
The radius \(\rho = ||\vec{q} - \vec{a}||\).

Assume edge \((\vec{a}, \vec{b})\) is the longest side of triangle.
Compute \(\vec{f} = (\vec{a} + \vec{b}) / 2\).
Define
\[
\vec{u} = \vec{a} - \vec{f}; \vec{v} = \vec{c} - \vec{f}
\]
\[
\vec{d} = (\vec{u} \times \vec{v}) \times \vec{u}
\]
Then the sphere center \(\vec{q}\) lies somewhere along the line
\[
\vec{q} = \vec{f} + \lambda \vec{d}
\]
with \((\lambda \vec{d} - \vec{v})^2 \leq (\lambda \vec{d} - \vec{u})^2\). Simplifying gives us
\[
\lambda \geq \frac{\vec{v}^2 - \vec{u}^2}{2 \vec{d} \cdot (\vec{v} - \vec{u})} = \gamma
\]
If \(\gamma \leq 0\), then just pick \(\lambda = 0\). Else pick \(\lambda = \gamma\).

Covariance Trees

Covariance Trees
Covariance Trees
Covariance Tree Construction

Given surface sample of \( N \) points \( \{ \mathbf{v}_i \} \)

Compute centroid \( \mathbf{p} = \frac{1}{N} \sum_{i=1}^{N} \mathbf{v}_i \)

Compute residual vectors \( \mathbf{u}_i = \mathbf{v}_i - \mathbf{p} \)

Define a local node coordinate system

\( \mathbf{F}_{\text{node}} = [\mathbf{R}, \mathbf{p}] \) and sort the surface points according to the sign of the \( x \) component of \( \mathbf{b}_j = \mathbf{R}^{-1} \cdot \mathbf{u}_j \). Compute bounding box

\( \mathbf{b}_{\text{min}} \leq \mathbf{R}^{-1} \cdot \mathbf{u}_j \leq \mathbf{b}_{\text{max}} \)

Assign these points to "left" and "right" subtree nodes.
Covariance Tree Construction

Form outer product matrix \( A = \sum_i \vec{u}_i \vec{u}_i^T \)

Compute eigenvalues \( \{ \lambda_1, \lambda_2, \lambda_3 \} \) and eigenvectors \( Q = [\vec{q}_1, \vec{q}_2, \vec{q}_3] \) of \( A \)

Find a rotation \( R \) such that \( R_{x} \) is the eigenvector corresponding to the largest eigenvalue.

(Depending on algorithm used, \( Q \) will be a rotation matrix, so all you may have to do is rotate \( Q \))

Constructing Cov Tree of Objects

```cpp
class CovTreeNode {
    Frame F;       // splitting point
    Vec3 UB;       // corners of box
    Vec3 LB;
    int HaveSubtrees;
    int nThings;
    CovTreeNode* SubTrees[2];
    Thing** Things;
    :
    :
    CovTreeNode(Thing** Ts, int nT);
    ConstructSubtrees();
    void FindClosestPoint(Vec3 v, double& bound, Vec3& closest);
};
```
Constructing Cov Tree of Things

CovTreeNode(Thing** Ts, int nT)
{   Things = Ts; nThings = nT;
    F = ComputeCovFrame(Things,nThings);
    [UB,LB] = FindBoundingBox(F,Things,nThings);
    ConstructSubtrees();
};

[vec3 UB,vec3 LB]=FindBoundingBox(F,Things,nThings)
{ UB = LB = F.inverse()*(Things[0]-SortPoint());
    for (int k=0;k<nThings;k++)
    { [LB,UB] = Things[k]->EnlargeBounds(F,LB,UB);
    }
    return [UB,LB];
};

Constructing Cov Tree of Things

Frame F = FindCovFrame(Thing** Ts, int nT)
{   [vec3 Points, int nP] = ExtractPoints(Ts,nT);
    // may extract nT sort points or perhaps
    // all corner points if things are triangles
    return FindCovFrame(Points,nP);
};

Frame F = FindCovFrame(vec3* Ps, int nP)
{   vec3 C = Centroid(Ps,nP);
    Matrix A = 0;
    for (i=0;i<nP;i++) A+=OuterProduct(Ps[i],Ps[i]);
    R = CorrespondingRotationMatrix(A);  // see notes
    return Frame(R,C);
};
Constructing Cov Tree of Things

{  if (nThings<= minCount || length(UB-LB)<=minDiag)
    { HaveSubtrees=0; return; };  
  HaveSubtrees = 1;
  int nSplit;
  nSplit = SplitSort(F,things);
  Subtrees[0] = CovarianceTreeNode(Things[0],nSplit);
  Subtrees[1] = CovarianceTreeNode(Things[nSplit],nThings-nSplit);
}

Int nSplit = SplitSort(Frame F, Thing** Ts,int nT)
{  // find an integer nSplit and reorder Things(…) so that
    // F.inverse()*(Thing[k]->SortPoint()).x <0 if and only if k<nSplit
    // This can be done “in place” by suitable exchanges.
    return nSplit;
}
Covariance tree search

Given
- node with associated $F_{node}$ and surface sample points $\vec{s}_i$.
- sample point $\vec{a}$, previous closest point $\vec{c}$, $dist = \|\vec{a} - \vec{c}\|$

Transform $\vec{a}$ into local coordinate system $\vec{b} = F_{node}^{-1} \vec{a}$

Check to see if the point $\vec{b}$ is inside an enlarged bounding box $\vec{b}^\text{min} - dist \leq \vec{b} \leq \vec{b}^\text{max} + dist$. If not, then quit.
Otherwise, if no subnodes, do exhaustive search for closest.
Otherwise, search left and right subtrees.

Searching a Covariance Tree of Things

```c
void CovarianceTreeNode::FindClosestPoint
    (Vec3 v, double& bound, Vec3& closest)
{
    vLocal=F.Inverse()'*v; // transform v to local coordinate system
    if (vLocal.x > UB.x+bound) return;
    if (vLocal.y > UB.y+bound) return;
    // similar checks on remaining bounds go here .... ;
    if (vLocal.z < LB.z-bound) return;
    if (HaveSubtrees)
    { Subtrees[0].FindClosestPoint(v,bound,closest);
        Subtrees[1].FindClosestPoint(v,bound,closest);
    }
    else
    for (int i=0;i<nThings;i++)
        UpdateClosest(Things[i],v,bound,closest);
};
```
Searching a Covariance Tree of Things

void UpdateClosest(Thing* T, Vec3 v, double& bound, Vec3& closest)
{  // here can include filter if have a bounding sphere to check
    Vec3 cp = T->ClosestPointTo(v);
    dist = LengthOf(cp-v);
    if (dist<bound) { bound = dist; closest=cp;};
};

Covariance Trees for Triangle Meshes

• One method is simply to place a bounding sphere around each triangle, and then use the method discussed previously
• However, this may be inconvenient if the mesh is deforming
Covariance Trees for Triangle Meshes

Observe that every point $\mathbf{v}$ on a triangle $[\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3]$ can be expressed as a convex linear combination $\mathbf{v} = \lambda_1 \mathbf{v}_1 + \lambda_2 \mathbf{v}_2 + \lambda_3 \mathbf{v}_3$ with $\lambda_1 + \lambda_2 + \lambda_3 = 1$. Therefore, if $[\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3]$ are in some bounding box, then $\mathbf{v}$ will also be in that bounding box.

Select one point on the triangle to use as the “sort” point for selection of left/right subtrees.

- Good choices are centroid of triangle or just one of the vertices.
- However use all vertices of each triangle in determining the size of bounding boxes.
- Note this would work equally well for octrees.
• Select one point on the triangle to use as the “sort” point for selection of left/right subtrees.
• Good choices are centroid of triangle or just one of the vertices.
• However use all vertices of each triangle in determining the size of bounding boxes.
• Note this would work equally well for octrees.

- Note this would work equally well for octrees.

An Alternative to Bounding Boxes: Bounding Ellipsoids

Compute

\[ \tilde{p}_c = \frac{1}{N} \sum_i \tilde{v}_i \]
\[ \tilde{u}_i = \tilde{v}_i - \tilde{p}_c \]
\[ A = \sum_i \tilde{u}_i \tilde{u}_i^T = Q \Lambda Q^T \]
\[ \Lambda = \text{diag}(\tilde{\lambda}) \]
\[ \rho^2 = \max_i \tilde{u}_i^T A \tilde{u}_i \]

Given a search point \( \tilde{d} \) and previous closest distance \( \delta \), the ellipsoid may have a closer point if

\[ (\tilde{d} - \tilde{p}_c)^T A (\tilde{d} - \tilde{p}_c) < \rho^2 + (\delta \max_k \tilde{\lambda}_k)^2 \]

**Note:** can probably get a tighter bound, but this will work
