CS 318 Principles of Operating Systems

Fall 2017

Lecture 2: Architecture Support for OS

Ryan Huang

Administrivia

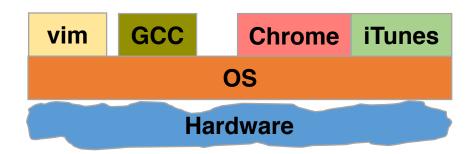

Lab 0

- Due 09/14, done individually

Project groups

- Fill out Google form (link in Piazza post)
- Just need one per group
- Fill out even if you are working alone

Why Start With Hardware?

- OS functionality depends upon the architectural features of H/W
 - Key goals of an OS are to enforce protection and resource sharing
 - If done well, applications can be oblivious to HW details
- Architectural support can greatly simplify or complicate OS tasks
 - Early PC operating systems (DOS, MacOS) lacked virtual memory in part because the architecture did not support it
 - Early Sun 1 computers used two M68000 CPUs to implement virtual memory (M68000 did not have VM hardware support)

Architectural Features for OS

Features that directly support the OS include

- Bootstrapping (Lab 0)
- Protection (kernel/user mode)
- Protected instructions
- Memory protection
- System calls
- Interrupts and exceptions
- Timer (clock)
- I/O control and operation
- Synchronization

Types of Arch Support

Manipulating privileged machine state

- Protected instructions
- Manipulate device registers, TLB entries, etc.

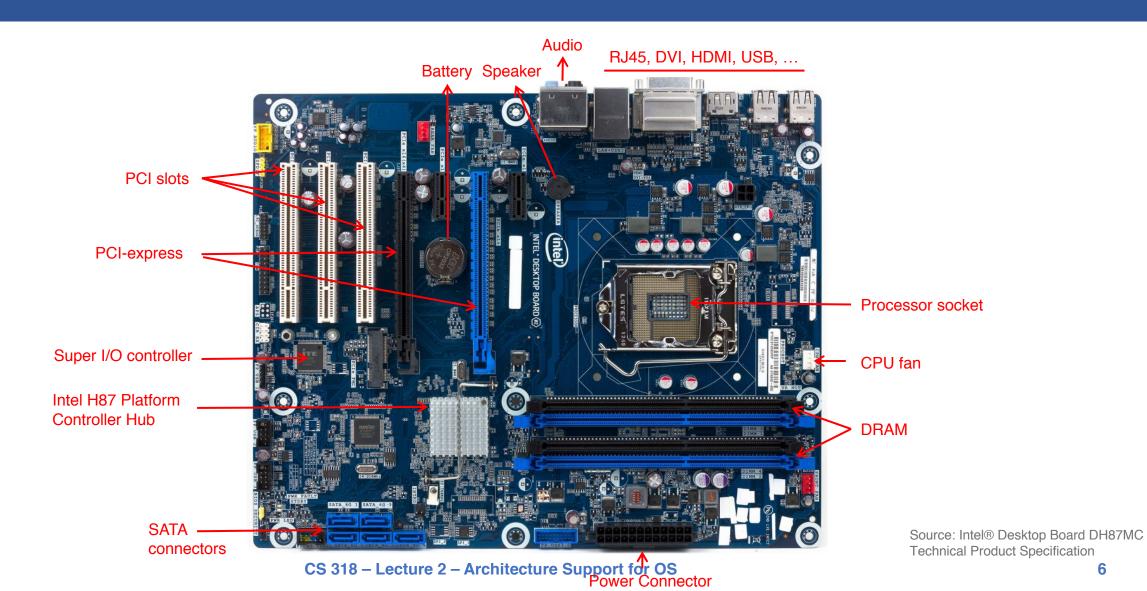

Generating and handling "events"

- Interrupts, exceptions, system calls, etc.
- Respond to external events
- CPU requires software intervention to handle fault or trap

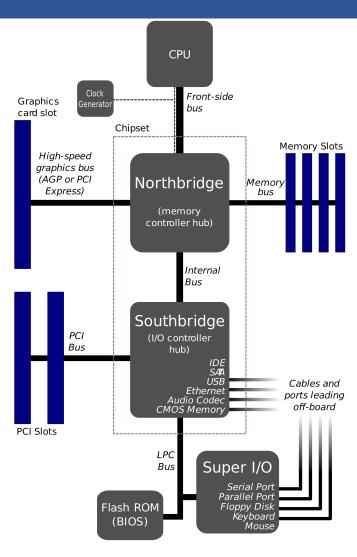

Mechanisms to handle concurrency

- Interrupts, atomic instructions

A Motherboard (Intel DH87MC)

Typical PC System Architecture

Thought Experiment: A World of Anarchy

Any program in the system can...

- Directly access I/O devices
- Write anywhere in memory
- Read content from any memory address
- Execute machine halt instruction

Do you trust such system?

- use Facebook
- run Banking app

Challenge: protection

- How to execute code with restricted privilege

Thought Experiment: A Solution

How can we implement execution with limited privilege?

- Execute each program instruction through a simulator (OS)
- If the instruction is permitted, do the instruction
- Otherwise, stop the process
- Basic model in Javascript and other interpreted languages

• How do we go faster?

- Most instructions are perfectly safe!
- Run the unprivileged code directly on the CPU
- Do the check in h/w

H/W Support: Dual-Mode Operation in CPU

User mode

- Limited privileges
- Only those granted by the operating system kernel

Kernel mode

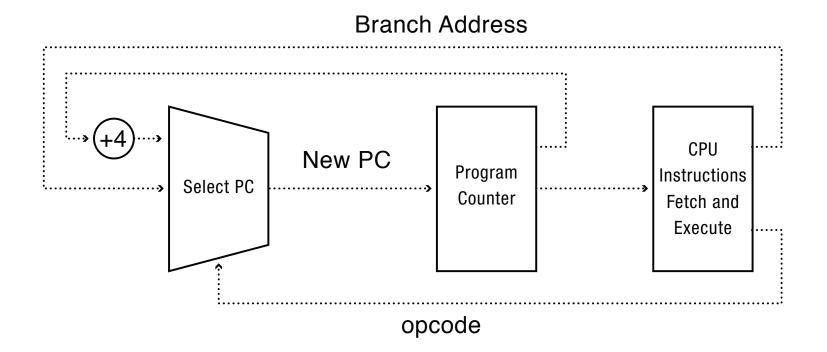

- Execution with the full privileges of the hardware
- Read/write to any memory, access any I/O device, read/write any disk sector, send/read any packet
- On the x86, mode stored in EFLAGS register
- On the MIPS, mode in the status register

A Simple Model of a CPU

Basic operation

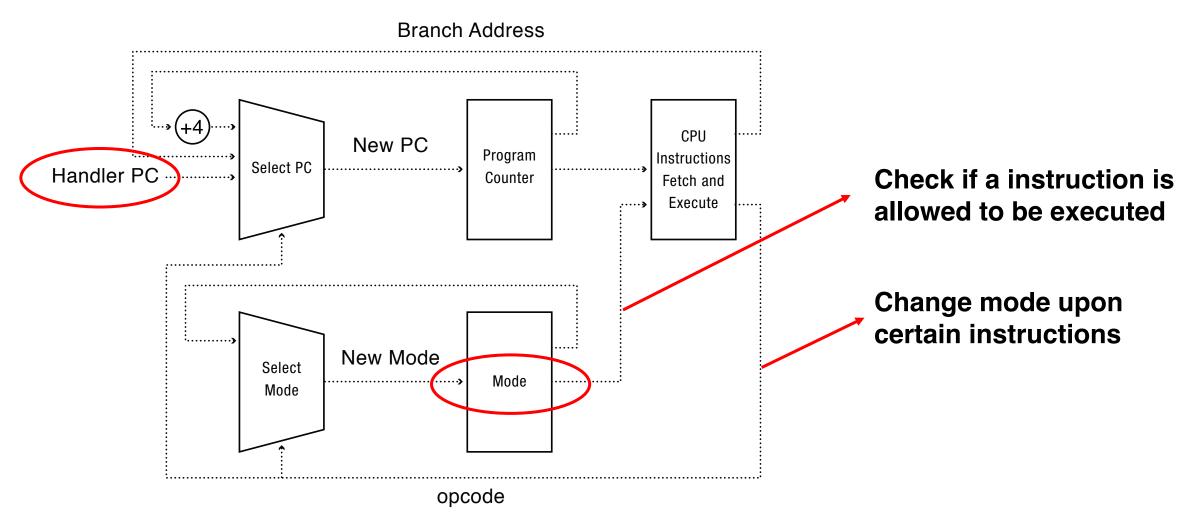

- Fetch next instruction → Decode instruction → Execute →

add/subtract, read/write memory, call function, branch...

A CPU with Dual-Mode Operation

Protected Instructions

- A subset of instructions restricted to use only by the OS
 - Known as protected (privileged) instructions
- Only the operating system can ...
 - Directly access I/O devices (disks, printers, etc.)
 - Security, fairness (why?)
 - Manipulate memory management state
 - Page table pointers, page protection, TLB management, etc.
 - Manipulate protected control registers
 - Kernel mode, interrupt level
 - Halt instruction (why?)

INVLPG—Invalidate TLB Entries

Opcode	Instruction		64-Bit Mode	Compat/ Leg Mode	Description
0F 01/7	INVLPG m	М	Valid	Valid	Invalidate TLB entries for page containing $\emph{m}.$

NOTES:

Instruction Operand Encoding

Op/En	Operand 1	Operand 2	Operand 3	Operand 4
М	ModRM:r/m (r)	NA	NA	NA

Description

Invalidates any translation lookaside buffer (TLB) entries specified with the source operand. The source operand is a memory address. The processor determines the page that contains that address and flushes all TLB entries for that page.¹

The INVLPG instruction is a privileged instruction. When the processor is running in protected mode, the CPL must be 0 to execute this instruction.

The INVLPG instruction normally flushes TLB entries only for the specified page; however, in some cases, it may flush more entries, even the entire TLB. The instruction is guaranteed to invalidates only TLB entries associated with the current PCID. (If PCIDs are disabled — CR4.PCIDE = 0 — the current PCID is 000H.) The instruction also invalidates any global TLB entries for the specified page, regardless of PCID.

For more details on operations that flush the TLB, see "MOV—Move to/from Control Registers" and Section 4.10.4.1, "Operations that Invalidate TLBs and Paging-Structure Caches," of the Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A.

This instruction's operation is the same in all non-64-bit modes. It also operates the same in 64-bit mode, except if the memory address is in non-canonical form. In this case, INVLPG is the same as a NOP.

IA-32 Architecture Compatibility

^{*} See the IA-32 Architecture Compatibility section below.

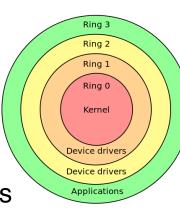

Beyond Dual-Mode Operations

(Modern) CPU may provide more than 2 privilege levels

- Called hierarchical protection domains or protection rings
 - higher-privilege rings can access lower-privilege operations and data
- x86 supports four levels:
 - ring 0 = kernel mode, ring 3 = user mode
- Multics provides 8 levels of privilege
- Even seen in mobile devices
 - ARMv7 processors in modern smartphones have 8 different protection levels

• Why?

- Protect the OS from itself (software engineering)
- reserved for vendor, e.g., virtualization

Memory Protection

• Why?

- OS must be able to protect programs from each other
- OS must protect itself from user programs

May or may not protect user programs from OS

- Raises question of whether programs should trust the OS
- Untrusted operating systems? (Intel SGX)

Memory management hardware (MMU) provides the mechanisms

- Base and limit registers
- Page table pointers, page protection, segmentation, TLB
- Manipulating the hardware uses protected (privileged) operations

Simple Memory Protection

 Memory access bounds check Physical Memory Base **Physical** Address Processor Base Base+ **Bound Bound**

Simple Memory Protection

Memory access bounds check

Problem

- Inflexible:
 - fix allocation, difficult to expand head and stack
- Memory sharing
- Memory fragmentation
- Physical memory
 - require changes to mem instructions each time the program is loaded

Idea: Virtual Address

Programs refer to memory by virtual addresses

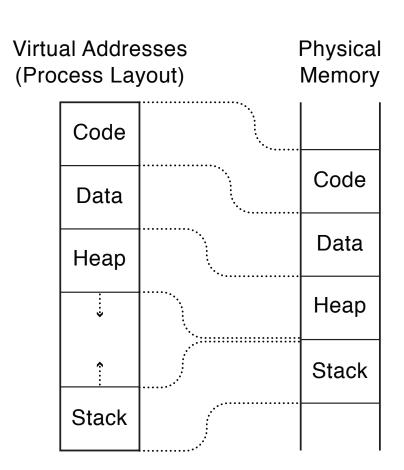

- start from 0
- illusion of "owning" the entire memory address space

The virtual address is translated to physical address

- upon each memory access
- done in hardware using a table
- table setup by the OS

Idea: Virtual Address

- Programs refer to memory by virtual addresses
 - start from 0
 - illusion of "owning" the entire memory address space
- The virtual address is translated to physical address
 - upon each memory access
 - done in hardware using a table
 - table setup by the OS

Types of Arch Support

- Manipulating privileged machine state
 - Protected instructions
 - Manipulate device registers, TLB entries, etc.
- Generating and handling "events"
 - Interrupts, exceptions, system calls, etc.
 - Respond to external events
 - CPU requires software intervention to handle fault or trap
- Mechanisms to handle concurrency
 - Interrupts, atomic instructions

OS Control Flow

After OS booting, all entry to kernel is a result of some event

- event immediately stops current execution
- changes mode to kernel mode
- invoke a piece of code to handle event (event handler)

When the processor receives an event of a given type, it

- transfers control to handler within the OS
- handler saves program state (PC, regs, etc.)
- handler executes core functionality
 - e.g., writing data to disk
- handler restores program state, returns to program

Events

An event is an "unnatural" change in control flow

- Events immediately stop current execution
- Changes mode, context (machine state), or both

The kernel defines a handler for each event type

- The specific types of events are defined by the architecture
 - e.g., timer event, I/O interrupt, system call trap
- In effect, the operating system is one big event handler

Event: Interrupt vs. Exceptions

- Two kinds of events, interrupts and exceptions
- Interrupts are caused by an external event (asynchronous)
 - Device finishes I/O, timer expires, etc.
- Exceptions are caused by executing instructions (synchronous)
 - CPU requires software intervention to handle a fault or trap
 - e.g., the x86 INT instruction
 - e.g., a page fault, write to a read-only page
 - a deliberate exception is a "trap", unexpected is a "fault"

Interrupts

Interrupts signal asynchronous events

- Indicates some device needs services
- I/O hardware interrupts
- Software and hardware timers

• Why?

- A computer is more than CPU
 - keyboard, disk, printer, camera, etc.
- These devices occasionally need attention
 - but can't predict when

Possible Solution: Polling

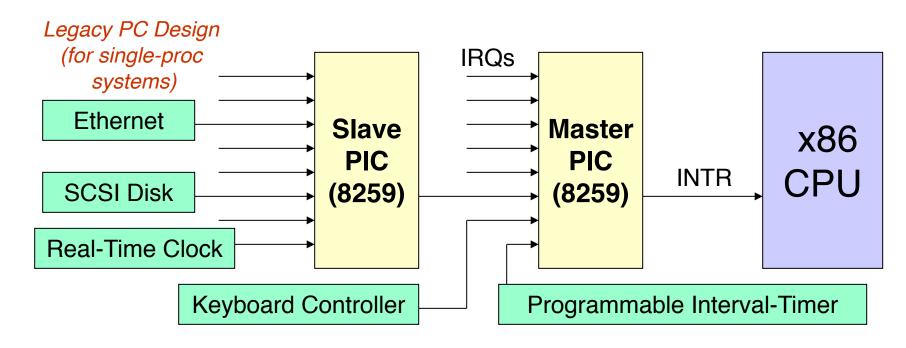

CPU periodically checks if each device needs service

- X takes CPU time when there are no events pending
- X can reduce checking overhead but at the expense of longer response time
- can be efficient if events arrive rapidly

"Polling is like picking up your phone every few seconds to see if you have a call..."

"Interrupts are like waiting for the phone to ring."

Interrupt Hardware

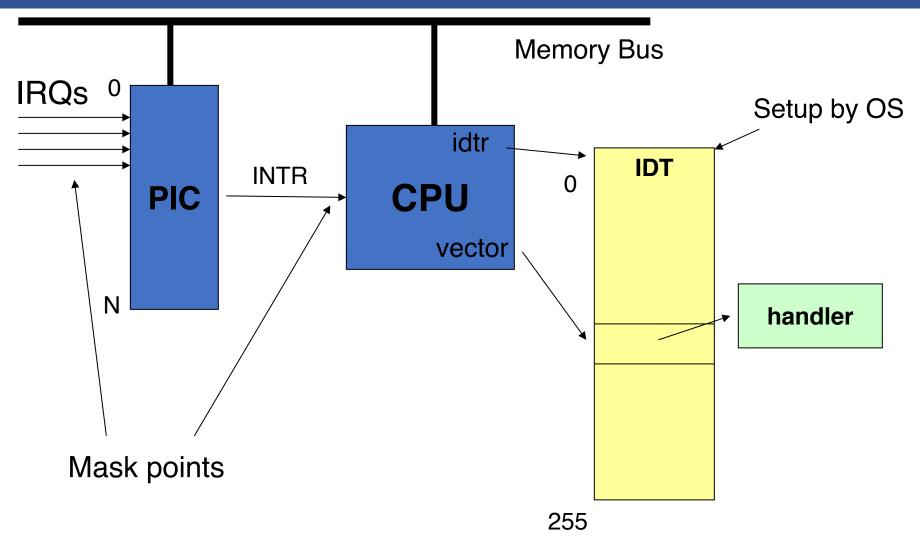

- I/O devices have (unique or shared) Interrupt Request Lines (IRQs)
- IRQs are mapped by special hardware to interrupt vectors, and passed to the CPU
- This hardware is called a Programmable Interrupt Controller (PIC)

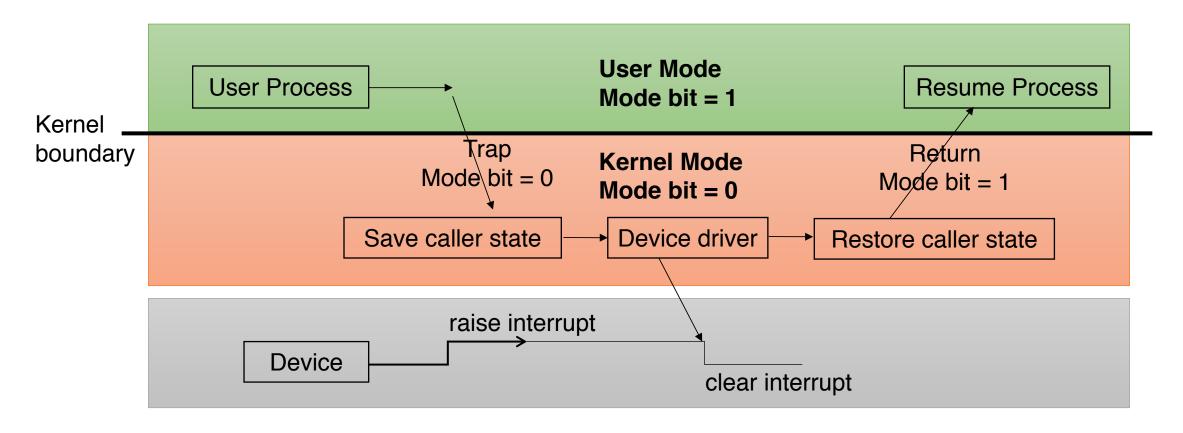

The "Interrupt Controller"

- PIC: Programmable Interrupt Controller (8259A)
 - Responsible for telling the CPU when and which device wishes to 'interrupt'
 - Has 16 wires to devices (IRQ0 IRQ15)
- PIC translates IRQs to vector number
 - Vector number is signaled over INTR line
 - In Pintos:
 - IRQ0...15 are delivered to interrupt vectors 32...47 (src/threads/interrupt.c)
- Interrupts can have varying priorities
 - PIC also needs to prioritize multiple requests
- Possible to "mask" (disable) interrupts at PIC or CPU

Putting It All Together

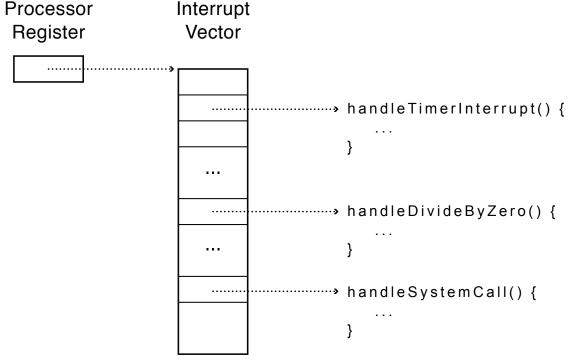

An Interrupt Illustrated

© 2004-2007 Ed Lazowska, Hank Levy, Andrea and Remzi Arpaci-Dussea, Michael Swift

Interrupt Vector Table (IVT)

- A data structure to associate interrupt requests with handlers
 - each entry is called an interrupt vector (specifies the address of the handler)
 - architecture-specific implementation

Interrupt Vector Table (IVT)

A data structure to associate interrupt requests with handlers

- each entry is called an interrupt vector (specifies the address of the handler)
- architecture-specific implementation

In x86 called Interrupt Descriptor Table (IDT)

- supports 256 interrupts, so the IDT contains 256 entries
- each entry specifies the address of the handler plus some flags
- programmed by the OS
 - In Pintos: make intr gate (src/threads/interrupt.c)

I/O Control

I/O issues

- Initiating an I/O
- Completing an I/O

Initiating an I/O

- Special instructions
- Memory-mapped I/O
 - Device registers mapped into address space
 - Writing to address sends data to I/O device

I/O Completion

Interrupts are the basis for asynchronous I/O

- OS initiates I/O
- Device operates independently of rest of machine
- Device sends an interrupt signal to CPU when done
- OS maintains a vector table containing a list of addresses of kernel routines to handle various events
- CPU looks up kernel address indexed by interrupt number, context switches to routine

I/O Example

- 1. Ethernet receives packet, writes packet into memory
- 2. Ethernet signals an interrupt
- 3. CPU stops current operation, switches to kernel mode, saves machine state (PC, mode, etc.) on kernel stack
- 4. CPU reads address from vector table indexed by interrupt number, branches to address (Ethernet device driver)
- Ethernet device driver processes packet (reads descriptors to find packet in memory)
- 6. Upon completion, restores saved state from stack

Timer

- The timer is critical for an operating system
- It is the fallback mechanism for OS to reclaim control over the machine
 - Timer is set to generate an interrupt after a period of time
 - Setting timer is a privileged instruction
 - When timer expires, generates an interrupt
 - Handled by kernel, which controls resumption context
 - Basis for OS scheduler (more later...)
- Prevents infinite loops
 - OS can always regain control from erroneous or malicious programs that try to hog CPU
- Also used for time-based functions (e.g., sleep())

Event: Interrupt vs. Exceptions

- Two kinds of events, interrupts and exceptions
- Interrupts are caused by an external event (asynchronous)
 - Device finishes I/O, timer expires, etc.
- Exceptions are caused by executing instructions (synchronous)
 - CPU requires software intervention to handle a fault or trap
 - e.g., the x86 INT instruction
 - e.g., a page fault, write to a read-only page
 - a deliberate exception is a "trap", unexpected is a "fault"

Deliberate Exception: Trap

A trap is an intentional software-generated exception

- the main mechanism for programs to interact with the OS
- On x86, programs use the int instruction to cause a trap
- On ARM, SVC instruction

Handler for trap is defined in interrupt vector table

- Kernel chooses one vector for representing system call trap
- e.g., int \$0x80 is used to in Linux to make system calls
- Pintos uses int \$0x30 for system call trap

System Call Trap

For a user program to "call" OS service

- Known as crossing the protection boundary, or protected control transfer

The system call instruction

- Causes an exception, which vectors to a kernel handler
- Passes a parameter determining the system routine to call

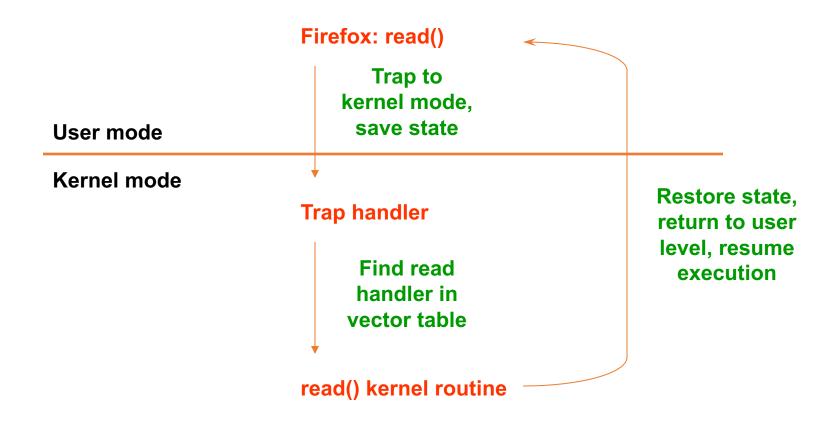

```
movl $20, %eax # Get PID of current process
int $0x80 # Invoke system call!
# Now %eax holds the PID of the current process
```

- Saves caller state (PC, regs, mode) so it can be restored
- Returning from system call restores this state

Requires architectural support to:

- Restore saved state, reset mode, resume execution

System Call

LINUX System Call Quick Reference

Jialong He
Jialong he@bigfoot.com
http://www.bigfoot.com/~jialong_he

Introduction

System call is the services provided by Linux kernel. In C programming, it often uses functions defined in **libe** which provides a wrapper for many system calls. Manual page section 2 provides more information about system calls. To get an overview, use "man 2 intro" in a command shell.

It is also possible to invoke syscall() function directly. Each system call has a function number defined in <syscall.h>or <unistd.h>. Internally, system call is invoked by software interrupt 0x80 to transfer control to the kernel. System call table is defined in Linux kernel source file "arch/386/kernel/entry.S".

System Call Example

```
#include <syscall.h>
#include <unistd.h>
#include <stdio.h>
#include <sys/types.h>
int main(void) {
      long ID1, ID2;
      /*----*/
      /* direct system call
      /* SYS getpid (func no. is 20) */
      /*----*/
      ID1 = syscall(SYS getpid);
      printf ("syscall(SYS_getpid)=%ld\n", ID1);
      /*----*/
      /* "libc" wrapped system call */
      /* SYS_getpid (Func No. is 20) */
      /*----*/
      ID2 = getpid();
      printf ("getpid()=%ld\n", ID2);
      return(0);
```

System Call Quick Reference

No	Func Name	Description	Source
1	exit	terminate the current process	kernel/exit.c
2	<u>fork</u>	create a child process	arch/i386/kernel/process.c
3	read	read from a file descriptor	fs/read_write.c
4	write	write to a file descriptor	fs/read_write.c
5	open	open a file or device	fs/open.c
6	close	close a file descriptor	fs/open.c
7	waitpid	wait for process termination	kernel/exit.c

8	<u>creat</u>	create a file or device ("man 2 open" for information)	fs/open.c
9	<u>link</u>	make a new name for a file	fs/namei.c
10	<u>unlink</u>	delete a name and possibly the file it refers to	fs/namei.c
11	execve	execute program	arch/i386/kernel/process.c
12	<u>chdir</u>	change working directory	fs/open.c
13	time	get time in seconds	kernel/time.c
14	mknod	create a special or ordinary file	fs/namei.c
15	chmod	change permissions of a file	fs/open.c
16	lchown	change ownership of a file	fs/open.c
18	stat	get file status	fs/stat.c
19	lseek	reposition read/write file offset	fs/read_write.c
20	getpid	get process identification	kernel/sched.c
21	mount	mount filesystems	fs/super.c
22	umount	unmount filesystems	fs/super.c
23	setuid	set real user ID	kernel/sys.c
24	getuid	get real user ID	kernel/sched.c
25	stime	set system time and date	kernel/time.c
26	ptrace	allows a parent process to control the execution of a child process	arch/i386/kernel/ptrace.c
27	<u>alarm</u>	set an alarm clock for delivery of a signal	kernel/sched.c
28	fstat	get file status	fs/stat.c
29	pause	suspend process until signal	arch/i386/kernel/sys_i386.c
30	utime	set file access and modification times	fs/open.c
33	access	check user's permissions for a file	fs/open.c
34	nice	change process priority	kernel/sched.c
36		- 1-1-1-1-1	
37	sync	update the super block	fs/buffer.c
	kill	send signal to a process	fs/buffer.c kernel/signal.c
38			
38 39	kill	send signal to a process	kernel/signal.c
	kill rename	send signal to a process change the name or location of a file	kernel/signal.c fs/namei.c
39	kill rename mkdir	send signal to a process change the name or location of a file create a directory	kernel/signal.c fs/namei.c fs/namei.c
39 40	kill rename mkdir rmdir	send signal to a process change the name or location of a file create a directory remove a directory	kernel/signal.c fs/namei.c fs/namei.c fs/namei.c
39 40 41	kill rename mkdir rmdir dup	send signal to a process change the name or location of a file create a directory remove a directory duplicate an open file descriptor	kernel/signal.c fs/namei.c fs/namei.c fs/namei.c fs/fcntl.c
39 40 41 42	kill rename mkdir rmdir dup pipe	send signal to a process change the name or location of a file create a directory remove a directory duplicate an open file descriptor create an interprocess channel	kernel/signal.c fs/namei.c fs/namei.c fs/namei.c fs/fcntl.c arch/i386/kernel/sys_i386.c
39 40 41 42 43	kill rename mkdir rmdir dup pipe times	send signal to a process change the name or location of a file create a directory remove a directory duplicate an open file descriptor create an interprocess channel get process times change the amount of space allocated for the	kernel/signal.c fs/namei.c fs/namei.c fs/namei.c fs/fcntl.c arch/i386/kernel/sys_i386.c kernel/sys.c
39 40 41 42 43	kill rename mkdir rmdir dup pipe times brk	send signal to a process change the name or location of a file create a directory remove a directory duplicate an open file descriptor create an interprocess channel get process times change the amount of space allocated for the calling process's data segment	kernel/signal.c fs/namei.c fs/namei.c fs/namei.c fs/fcntl.c arch/i386/kernel/sys_i386.c kernel/sys.c mm/mmap.c
39 40 41 42 43 45	kill rename mkdir rmdir dup pipe times brk setgid	send signal to a process change the name or location of a file create a directory remove a directory duplicate an open file descriptor create an interprocess channel get process times change the amount of space allocated for the calling process's data segment set real group ID	kernel/signal.c fs/namei.c fs/namei.c fs/namei.c fs/namei.c fs/fcntl.c arch/i386/kernel/sys_i386.c kernel/sys.c mm/mmap.c kernel/sys.c
39 40 41 42 43 45 46 47	kill rename mkdir rmdir dup pipe times brk setgid getgid	send signal to a process change the name or location of a file create a directory remove a directory duplicate an open file descriptor create an interprocess channel get process times change the amount of space allocated for the calling process's data segment set real group ID get real group ID	kernel/signal.c fs/namei.c fs/namei.c fs/namei.c fs/fcntl.c arch/i386/kernel/sys_i386.c kernel/sys.c mm/mmap.c kernel/sys.c kernel/sys.c

create a file or device ("man 2 open" for

fs/open.c

9/7/17 get effective group ID Remeusched.c 41

System Call Questions

- What would happen if the kernel did not save state?
- What if the kernel executes a system call?
- What if a user program returns from a system call?
- How to reference kernel objects as arguments or results to/from syscalls?
 - A naming issue
 - Use integer object handles or descriptors
 - E.g., Unix file descriptors, Windows HANDLEs
 - Only meaningful as parameters to other system calls
 - Also called capabilities (more later when we do protection)
 - Why not use kernel addresses to name kernel objects?

Unexpected Exception: Faults

- Hardware detects and reports "exceptional" conditions
 - Page fault, unaligned access, divide by zero
- Upon exception, hardware "faults" (verb)
 - Must save state (PC, regs, mode, etc.) so that the faulting process can be restarted
- Modern OSes use VM faults for many functions
 - Debugging, end-of-stack, garbage collection, copy-on-write
- Fault exceptions are a performance optimization
 - Could detect faults by inserting extra instructions into code (at a significant performance penalty)

Handling Faults

Some faults are handled by "fixing"....

- "Fix" the exceptional condition and return to the faulting context
- Page faults cause the OS to place the missing page into memory
- Fault handler resets PC of faulting context to re-execute instruction that caused the page fault

Some faults are handled by notifying the process

- Fault handler changes the saved context to transfer control to a user-mode handler on return from fault
- Handler must be registered with OS
- Unix signals or Win user-mode Async Procedure Calls (APCs)
 - SIGALRM, SIGHUP, SIGTERM, SIGSEGV, etc.

Handling Faults (2)

Kernel may handle unrecoverable faults by killing the process

- Program fault with no registered handler
- Halt process, write process state to file, destroy process
- In Unix, the default action for many signals (e.g., SIGSEGV)

What about faults in the kernel?

- Dereference NULL, divide by zero, undefined instruction
- These faults considered fatal, operating system crashes
- Unix panic, Windows "Blue screen of death"
 - Kernel is halted, state dumped to a core file, machine locked up

Types of Arch Support

Manipulating privileged machine state

- Protected instructions
- Manipulate device registers, TLB entries, etc.

Generating and handling "events"

- Interrupts, exceptions, system calls, etc.
- Respond to external events
- CPU requires software intervention to handle fault or trap

Mechanisms to handle concurrency

- Interrupts, atomic instructions

Synchronization

Interrupts cause difficult problems

- An interrupt can occur at any time
- A handler can execute that interferes with code that was interrupted
- OS must be able to synchronize concurrent execution
- Need to guarantee that short instruction sequences execute atomically
 - Disable interrupts turn off interrupts before sequence, execute sequence, turn interrupts back on
 - Special atomic instructions read/modify/write a memory address, test and conditionally set a bit based upon previous value
 - XCHG instruction on x86

Summary

Protection

- User/kernel modes
- Protected instructions

Interrupts

- Timer, I/O

	Unexpected	Deliberate
Exceptions (sync)	fault	syscall trap
Interrupts (async)	interrupt	software interrupt

System calls

- Used by user-level processes to access OS functions
- Access what is "in" the OS

Exceptions

Unexpected event during execution (e.g., divide by zero)
