

Min-Makespan on Identical Parallel Machines

Input: Jobs J ($|J| = n$)

- Machines M ($|M| = k$)

- Processing times $p: J \rightarrow \mathbb{N}$

Feasible Solution: $\mathbb{I}: J \rightarrow M$

Objective: min makespan $= \min_{m \in M} \max \sum_{j \in J: \mathbb{I}(j) = m} p(j)$

Thm: Greedy is a 2-approximation.

want to do better!

Idea: What if we have a "guess" T for OPT ?

Def: A $(1+\epsilon)$ -relaxed decision procedure is an algorithm which, given input and T :

- 1) If $T \geq OPT$, returns a solution with makespan $\leq (1+\epsilon)T$
- 2) If $T < OPT$, either returns "false" or returns a solution with makespan $\leq (1+\epsilon) \cdot OPT$

Let $P = \sum_{i \in J} p(i)$. Then $1 \leq OPT \leq P$

Idea: do binary search to find value of T s.t.
procedure returns a solution on T , "false" on $T-1$

$$\Rightarrow T \leq OPT$$

$$\Rightarrow \text{solution has makespan} \leq (1+\epsilon) \cdot OPT$$

Takes $O(\log P)$ iterations: polytime!

So just want to design such a procedure, given guess T .

$$\text{Def: } J_{\text{small}} = \{i \in J : p(i) \leq \epsilon T\}$$

$$J_{\text{large}} = \{i \in J : p(i) > \epsilon T\}$$

Thm: Given schedule for J_{large} with makespan $\leq (1+\epsilon)T$,
we can find a schedule for J with makespan
 $\leq (1+\epsilon) \max(T, OPT)$

PF:

Start with schedule for J_{large} .

Greedy on J_{small} :

- in arbitrary order, add job to least-loaded machine

Consider machine m .

- Case 1: m has no small jobs.

$$\Rightarrow \text{load} \leq (1+\epsilon)T$$

- Case 2: m has ≥ 1 small job

Greedy analysis:

Let j be last small job assigned to m

$$\Rightarrow p(j) \leq \epsilon \cdot T,$$

$$\text{load on } m \text{ just before } \leq OPT$$

$$\Rightarrow \text{total load} \leq OPT + \epsilon T \leq (1+\epsilon) \max(T, OPT)$$

So just need to schedule J_{large} with makespan $\leq (1+\epsilon)T$

Let $b = \lceil \frac{1}{\epsilon} \rceil$, so $\frac{1}{b} \leq \epsilon$

Def: Let $p'(j) = \left\lfloor \frac{p(j)b^2}{T} \right\rfloor \cdot \frac{T}{b^2}$ ("rounded instance")

p' is p rounded down to multiple of $\frac{T}{b^2}$

$$\Rightarrow p'(j) \leq p(j) \leq p'(j) + \frac{T}{b^2}$$

$$p'(j) = k \frac{T}{b^2} \text{ for some } k \in \{b, b+1, \dots, b^2\} \text{ (since } j \in J_{\text{large}})$$

For schedule \mathcal{J} , let $m(\mathcal{J})$ be makespan in original
 $m_r(\mathcal{J})$ makespan in rounded.

Lemma 1: Let \mathcal{J} schedule. Then $m_r(\mathcal{J}) \leq m(\mathcal{J})$

Pf:

$$p'(j) \leq p(j) \quad \forall j \in J$$

Lemma 2: Let \mathcal{J} schedule. Then
 $m(\mathcal{J}) \leq (1+\epsilon) m_r(\mathcal{J})$
 T

Pf:

Let m some machine

$$\text{since } p'(j) \geq \frac{T}{b}, \quad |I^{-1}(m)| \leq b$$

$$\begin{aligned} \Rightarrow \sum_{j \in I^{-1}(m)} p(j) &\leq \sum_{j \in I^{-1}(m)} \left(p'(j) + \frac{T}{b^2} \right) \\ &= \sum_{j \in I^{-1}(m)} p'(j) + \sum_{j \in I^{-1}(m)} \frac{T}{b^2} \\ &\quad \stackrel{\text{m}_r(I)}{=} \\ &\leq T + \frac{T}{b} \leq T + \varepsilon T = (1 + \varepsilon)T \end{aligned}$$

Suppose we had an algorithm to find some I
with $m_r(I) \leq T$ if one exists

If $T \geq \text{OPT}$:

$\exists I$ with $m(I) \leq T \Rightarrow m_r(I) \leq T$ (Lemma 1)

$\Rightarrow \exists$ schedule w/ makespan $\leq T$ in rounded

\Rightarrow alg will find some I' with $m_r(I') \leq T$

$\Rightarrow m(I') \leq (1 + \varepsilon)T$ (Lemma 2)

If $T < OPT$:

If alg returns \mathcal{I} , have

$$m(\mathcal{I}) \leq (1+\epsilon) T \quad (\text{Lemma 2})$$

So just need to find \mathcal{I} with $m(\mathcal{I}) \leq T$ if one exists!

Def: A **configuration** is a tuple $(a_1, a_{b+1}, \dots, a_{b^2})$

such that:

1) Each $a_i \in \{0, 1, \dots, b\}$

2) $\sum_{i=b}^{b^2} a_i \cdot i \cdot \frac{T}{b^2} \leq T$

Idea: Look at jobs assigned to some machine, let a_i be #

with $p'(i) = i \cdot \frac{T}{b^2}$

\Rightarrow get a configuration

Let $\mathcal{C}(T)$ be set of all configurations

$$|\mathcal{C}(T)| \leq (b+1)^{b^2-b} \approx (b)^{b^2}$$

Dynamic Programming: given (rounded) jobs, how many machines are necessary?

More formally:

$f(n_b, n_{b+1}, \dots, n_{b^2}) = \min m$ s.t. can schedule n_i jobs
of length $i \cdot \frac{T}{b^2}$ $\forall i$ with makespan $\leq T$

$$f(\vec{0}) = 0$$

$$f(n_b, \dots, n_{b^2}) =$$

$$1 + \min_{\vec{a} \in \mathcal{C}(T)} f(n_b - a_b, n_{b+1} - a_{b+1}, \dots, n_{b^2} - a_{b^2})$$

Time / table entry: $|\mathcal{C}(T)| \approx b^{b^2}$

table entries: $\leq n^{b^2}$

$$\Rightarrow \text{total time} \leq n^{O(k^2)} = n^{O((1/\epsilon)^2)}$$

Once table filled out, check entry corresponding to J_{large} (rounded)

If $> m$: no \mathbb{I} with $m_r(\mathbb{I}) \leq T$

\Rightarrow no \mathbb{I} with $m(\mathbb{I}) \leq T$

\Rightarrow return false

If $\leq m$: Return \mathbb{I} with $m_r(\mathbb{I}) \leq T$
