Abstract

We demonstrate a text to sign language translation system for investigating sign language (SL) structure and assisting in production of sign narratives and informative presentations¹. The system is demonstrable on a conventional PC laptop computer.

1 Introduction

During the last half century sign languages have been recognized as genuine languages. Thus sign languages are now accepted as minority languages, which coexist with majority languages (Neidle et al., 2000) and which are the native languages for many deaf people. Provision of information access and services in signed languages is as important as in other minority languages. Such provision, however, introduces theoretical and technical challenges. The use of a sign language gesture notation to drive virtual humans (avatars) for presenting signing has been investigated (Kennaway, 2001). Semi-automatic translation system from individual English sentences to such a sign language gesture notation has been demonstrated (self identify in references). Here, extension of this system to handle location of nominals at positions in the three dimensional space in front of the signer and noun verb agreement involving such allocated positions is described and illustrated.

¹This work is incorporated within ViSiCAST, an EU Framework V supported project which builds on work supported by the UK Independent Television Commission and Post Office.

2 Sign language phenomena

Sign Languages (SLs) involve simultaneous manual and non-manual components for conveying meaning. Non-manual features are comprised of the posture of the upper torso, the orientation of the head and facial expressions. Manual features have been often been decomposed as hand-shape, hand orientation, hand position and motion (Stokoe, 1978; Brien, 1992; Sutton-Spence and Woll, 1999). The Hamburg Notation System (HamNoSys) (Prillwitz et al., 1989; Hanke and Schmaling, 2001; Hanke, 2002) is an established phonetic transcription system for SLs comprising more than 200 iconically motivated symbols to describe these manual and non-manual features of signs.

The manual components of signs are constrained to occur within *signing space*. Signing space is the three-dimensional space in front of the signer which extends vertically from above the signer's head to waist level, and horizontally from touching/close to the body to at arm's length in front of and to the side of the signer. Signs can be categorised in terms of the ways they use signing space. Body anchored and fixed nominal and verbal signs are either signed at a fixed body location or involve internal motion which allow relatively little modification to the sign. In contrast, some nominal signs can be signed at varying locations and thus the location where they are signed has significance. Furthermore, directional verbs allow grammatical and semantic information to be encoded within signing space such that the specific start and/or end positions of these signs have syntactic and semantic significance (Liddel, 1990). A further distinction can be made between topographic and syntactic use of space (Klima and Bel-

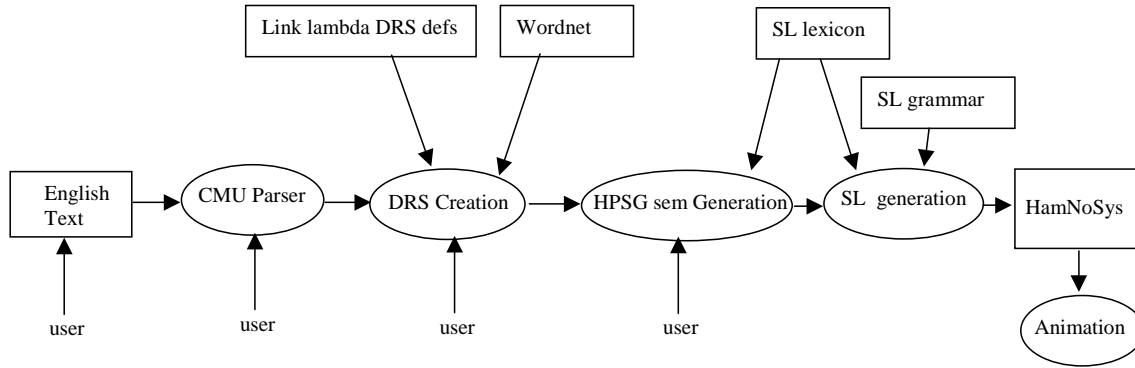

Figure 1: Architecture of the translation system

lugi, 1979; Emmorey et al., 1995; Sutton-Spence and Woll, 1999). In the case of the former, signing space is used to gesture towards and point at objects and persons physically present and thus has similarities with body anchored signs where the location at which a sign is made has an iconic/deictic function. However, in cases where the signer describes relationships between objects and persons which are not present, position within signing space can be used to denote abstract referents. Similarities between topographic and syntactic uses are apparent and often there is overlap between the two, and there is some evidence to suggest that, contrary to expectations, the granularity of the two may be comparable (Cormier, 2002). As our concerns are with translation from English text to sign language (and hence physical presence is not an issue) we concentrate on the syntactic uses of signing space.

3 System Architecture

The architecture of the English text to British Sign Language (BSL) system is essentially a pipeline of four main translation stages

1. English syntactic parsing,
2. Discourse Representation Structure (DRS) generation,
3. Semantic transfer,
4. Generation of HamNoSys SL phonetic descriptions,

as illustrated in Figure 1.

3.1 Syntactic Parsing

English text (Figure 2 top left) is parsed by the Carnegie Mellon University (CMU) link grammar

parser (Sleator and Temperley, 1991) to produce an appropriate *linkage* which characterises syntactic dependencies (Figure 2 bottom left). In cases where multiple linkages are generated, the user intervenes to select an appropriate linkage.

3.2 DRS Generation

From a CMU parser generated linkage a Discourse Representation Structure DRS (Kamp and Reyle, 1993) is generated to capture the semantic content of the text (Figure 2 top middle). DRSs allow isolation of specific semantic content (nominal, verbal and adjectival based predicates, discourse referents and temporal relationships). Anaphora resolution is used to associate pronouns with discourse referents, and reuse of nouns is used to imply co-reference to the same linguistic referent. Currently, the most common 50% CMU links are transformed into DRS form.

3.3 Semantic Transfer

An English oriented DRS is transformed into a SL oriented DRS. In particular, the number of arguments for some predicates is modified to a different number of arguments expected of a corresponding SL sign. For example, the English verb *move* obligatorily requires only one argument but is often accompanied by optional adjuncts for the source and destination locations. Its BSL equivalent (glossed as MOVE) requires three arguments - the start and end sign space positions and a (classifier or default) handshape consistent with the object being moved. Such transformations are effected on the DRS.

The DRS is then transformed to an equivalent

HPSG semantic structure which is the starting point for SL generation.

3.4 HamNoSys SL Generation

A SL grammar and lexicon are used to drive derivation of a HamNoSys phonetic description of a sign sequence from the HPSG semantic structure (Figure 2 bottom middle). The BSL lexicon contains approximately 250 lexical items. Some lexical items are fully instantiated forms for fixed and body-anchored signs, however others are only partially instantiated forms for directional verbs and forms of modulation of lexical items. For nominal oriented signs, *classifiers* are associated with signs, and for directional verbs the lexical entries require incorporation of specific forms of classifiers and sign space locations.

The SL grammar constitutes a collection of simul-

taneous constraints which the phonology and syntax of selected signs must satisfy in order to constitute a valid sign sequence. These constraints enforce appropriate sign order, for example realising a topic comment ordering signs for the English sentence "I saw an exciting video."

VIDEO EXCITING/INTERESTING SEE ME

Sign space location agreement requires that nominals are assigned consistent positions in signing space and that directional verbs agree with these positions that reflects anaphoric relationships of the original text and use with directional verbs. In this example, the directional verb SEE must start at the location of ME and be directed towards the location of VIDEO. Subsequent references to the same object must respect its position by signing the sign at the same location or by anaphoric pointing at that location. This form of agreement is achieved by in-

clusion of a model of signing space within the HPSG feature structure in which nominals are allocated positions and from which verbal signs acquire positional information (Figure 2 top right).

Number agreement between nominal and verbal signs is enforced distinguishing between collective and distributive interpretations of plurals. For example, the friends in "I invited four friends" may have been invited individually (in which case the directional verb INVITE is repeated three times) or they may have been invited as a group (with INVITE signed only once). The under-specification in the English input is resolved by requesting the user to volunteer the additional information of a distributive or collective reading.

Conclusions

The resulting HamNoSys sign sequence descriptions are realised visually as virtual human behaviour (Kennaway, 2001) (Figure 2 bottom right)². Currently, the SL generation sub-system incorporates a lexicon and grammar whose coverage are representative of a number of interesting SL phenomena and whose semantic, syntactic and phonological formalisation is one of the most advanced SL characterisations available. Such detail is essential to enable visualisation by a virtual human. The main omission in the system currently is the absence of non-manual components of signing, though the SL generation has been designed to be extended in this direction in the future. The functionality of the system is demonstrable on a laptop computer.
